PET refers to the PET 2001 Computer which is a registered trademark of Commodore Business Machines, Inc., 901 California Avenue, Palo Alto, California 94304.

Acknowledgements

Our thanks to the following for their help and encouragement:
Our wives and families, John Craig, Martin Cohen, Asenatha McCauley, Herb Furth, Freddie, Michael Richter, Wayne Green, Jay Balakrishnan, and everybody at the Computer Store in Santa Monica.

AN IMPORTANT NOTE

The publisher and authors have made every effort to assure that the computer programs and programming information in this publication are accurate and complete. However, this publication is prepared for general readership, and neither the publisher nor the authors have any knowledge about or ability to control any third party's use of the programs and programming information. There is no warranty or representation by either the publisher or the authors that the programs or programming information in this book will enable the reader or user to achieve any particular result.

Preface

You have bought yourself a Commodore PET 2001 computer (or maybe you just have access to one at school or work). You will soon find that the most frequent question you are asked goes something like this: “Oh, you got a computer, eh? Uh . . . what are you going to do with it?”

Your answer, of course, depends on your own particular situation. Maybe you got it for mathematical work, or for your business, or for home usage, or to enable you to learn more about computers. Maybe you got it for a teaching/learning tool or for playing games.

Even if you got the computer specifically for only one of these reasons, you should not neglect the others. The computer is such a powerful tool that it can be used in many different ways. If it is not being used for its “intended” function right now, why not make use of it in some other way?

The PET is so small and portable that you can, say, take it home from work over the weekend and let the kids play educational games. They will have fun *and* learn a lot. After they go to bed, you can use it to help plan your personal finances. Or, you can let your guests at a party try to outsmart the PET (or each other) at some fascinating games. The possibilities go on and on.

All these things can be done with the PET, but the PET cannot do any of them without the key ingredient—a computer program. People with little or no exposure to computers may be in for a surprise when they learn this. A computer without a program is like a car without a driver. It just sits there.

So you ask, "Where can I get some programs to do the things I want my computer to do?" Glad you asked. There are several alternatives.

1. Hire a computer programmer. If you have a big budget, this is the way to go. Good programmers are expensive and hard to find (and you will not know for sure if they're really good until after the job is finished). Writing a couple of programs that are moderately complex will probably cost you more than you paid for the PET itself.
2. Learn to program yourself. This is a nice alternative, but it takes time. There are lots of programming books available—some are good, some not so good. You can take courses at local colleges. If you can afford the time and you have a fair amount of common sense and inner drive, this is a good solution.
3. Buy the programs you want. This is cheaper than hiring your own programmer because all the buyers share the cost of writing the programs. You still will not find it very cheap, especially if you want to accumulate several dozen programs. Each program might cost anywhere from a few dollars to several hundred dollars. The main problem is that you cannot be sure how good the programs are, and, since they are generalized for all possible buyers, you may not be able to easily modify them to do exactly what *you* want. Also, they have to be written in a computer language that *your* computer understands. Even if you find a program written in the BASIC language, you will soon learn that the PET's BASIC is not the same as other versions. Variations between versions of the same language typically result in the program not working.

This book gives you the chance to take the third alternative at the lowest possible cost. If you divide the cost of the book by the number of programs in it (use your computer if you like), you will find that the cost per program is amazingly low. Even if there are only a few programs in the book that will be useful to you, the cost is pretty hard to beat.

Just as important is the fact that these programs are written specifically for your PET. If you type them in exactly as shown, they will work! No changes are needed. In addition, we show you exactly what to change in order to make some simple modifications that may suit your taste or needs. Plus, if you

have learned a little about BASIC, you can go even further and follow the suggestions about more extensive changes that can be made. This approach was used to try to make every program useful to you, whether you are a total beginner or an old hand with computers.

But enough of the sales pitch. Our main point is that we feel a computer is an incredibly flexible machine, and it is a shame to put it to only one or two limited uses and let it sit idle the rest of the time. We are giving you a pretty wide range of things to do with your PET, and we are really only scratching the surface.

So open your eyes and your mind. Play a mental game against the computer (WARI, JOT). Evaluate your next financial decision (LOAN, DECIDE). Expand your vocabulary or improve your reading speed (VOCAB, TACHIST). Solve mathematical equations (DIFFEQN, SIMEQN).

But please, don't leave your PET asleep in the corner too much. Give it some exercise.

How to Use This Book

Each chapter of this book presents a computer program that runs on an 8K Commodore PET 2001 computer. Most will also run on a 4K PET (see Appendix 1). Each chapter is made up of eight sections that serve the following functions:

1. **Purpose:** Explains what the program does and why you might want to use it.
2. **How To Use It:** Gives the details of what happens when you run the program. Explains your options and the meanings of any responses you might give. Provides details of any limitations of the program or errors that might occur.
3. **Sample Run:** Shows you what you will see on the screen when you run the program.
4. **Program Listing:** Provides a “listing” (or “print-out”) of the BASIC program. These are the instructions to the computer that you must provide so it will know what to do. You must type them in extremely carefully for correct results.
5. **Easy Changes:** Shows you some very simple changes you can make to the program to cause it to work differently, if you wish. You do not have to understand how to program to make these changes.
6. **Main Routines:** Explains the general logic of the program, in case you want to figure out how it works. Gives the BASIC line numbers and a brief explanation of what each major portion of the program accomplishes.
7. **Main Variables:** Explains what each of the key variables in the program is used for, in case you want to figure out how it works.

- 8. Suggested Projects:** Provides a few ideas for major changes you might want to make to the program. To try any of these, you will need to understand BASIC and use the information provided in the previous two sections (Main Routines and Main Variables).

To use any of these programs on your PET computer, you need only use the first four sections. The last four sections are there to give you supplementary information if you want to tinker with the program.

RECOMMENDED PROCEDURE

Here is our recommendation of how to try any of the programs in this book:

1. Read through the documentation that came with the PET to learn the fundamentals of communication with the computer. This will teach you how to turn the computer on, enter a program, correct mistakes, run a program, etc.
2. Pick a chapter and read Section 1 ("Purpose") to see if the program sounds interesting or useful to you. If not, move on to the next chapter until you find one that is. If you are a beginner you might want to try one of the short "Miscellaneous Programs" first.
3. Read Sections 2 and 3 of the chapter ("How To Use It" and "Sample Run") to learn the details of what the program does.
4. Enter the NEW command to eliminate any existing program that might already be in your PET's memory. Using Section 4 of the chapter ("Program Listing"), carefully enter the program into the PET. Be particularly careful to get all the punctuation characters right (i.e., commas, semicolons, colons, quotation marks, etc.).
5. After the entire program is entered into the PET's memory, use the LIST command to display what you have entered so you can double check for typographical errors, omitted lines, etc. Don't mistake a semicolon for a colon, or an alphabetic I or O for a numeric 1 or 0 (zero). Take a minute to note the differences in these characters before you begin.
6. Before trying to RUN the program, use the SAVE command to save the program temporarily on cassette. This could prevent a lot of wasted effort in case something goes wrong (power failure, PET malfunction, etc.).

7. Now RUN the program. Is the same thing happening that is shown in the Sample Run? If so, accept our congratulations and go on to step 9. If not, stay cool and go to step 8.
8. If you got a SYNTAX ERROR in a line, LIST that line and look at it closely. Something is not right. Maybe you interchanged a colon and a semicolon. Maybe you typed a numeric 1 or 0 instead of an alphabetic I or O. Maybe you misspelled a word or omitted one. Keep looking until you find it, then correct the error and go back to step 7.

If you got some other kind of error message, consult the PET documentation for an explanation. Keep in mind that the error might not be in the line that is pointed to by the error message. It is not unusual for the mistake to be in a line immediately preceding the error message line. Another possibility is that one or more lines were omitted entirely. In any event, fix the problem and go back to step 7.

If there are no error messages, but the program is not doing the same thing as the Sample Run, there are two possibilities. First, maybe the program isn't *supposed* to do exactly the same thing. Some of the programs are designed to do unpredictable things to avoid repetition (primarily the game programs and graphic displays). They should be doing the same *types* of things as the Sample Run, however.

The second possibility is that you made a typing error that did not cause an error message to be displayed, but simply changed the meaning of one or more lines in the program. These are a little tricky to find, but you can usually narrow it down to the general area of the problem by noting the point at which the error takes place. Is the first thing displayed correct? If so, the error is probably after the PRINT statement that caused the first thing to be displayed. Look for the same types of things mentioned before. Make the corrections and go back to step 7.

9. Continue running the program, trying to duplicate the Sample Run. If you find a variation that cannot be accounted for in the "How To Use It" section of the chapter, go to step 8. Otherwise, if it seems to be running properly, SAVE the program on cassette (using the same name as the title of the chapter), and VERIFY it.
10. Read Section 5 of the chapter ("Easy Changes"). Try any of the changes that look interesting. If you think the changed version is better, SAVE it on cassette, too. You will probably

want to give it a slightly different name from the original version to avoid future confusion. For example, try SAVE "VOCAB2" instead of SAVE "VOCAB".

A NOTE ON THE PROGRAM LISTINGS

A line on the screen of the PET is 40 characters wide. The printer that was used to create the Program Listing section of each chapter prints lines up to 80 characters long. For best reproduction in this book, it is preferable that each published line be no longer than 55 characters. This combination of facts might cause you a little confusion when you are copying the programs into your PET. Here's the way it works.

Wherever there is a line in a program that is longer than 55 characters, it has been divided into two lines that are each no more than 55 characters. You can recognize this easily because the second part has no line number at the left-hand side. This division is only for the purpose of printing the book. You should think of a divided line like this as one long line and enter it into your PET as a single line. Where possible, this division is made in such a way that the first part of the line ends with a colon so you can notice it more easily.

Don't be fooled by the fact that the cursor on your PET jumps down to the next line after you enter the 40th character—it's just one long line until you press **RETURN**.

Contents

How to Use This Book	xi
-----------------------------	-----------

Section 1—APPLICATIONS PROGRAMS

Practical uses at home or work.

BIORHYTHM	<i>Can you predict your good and bad days?</i>	3
CHECKBOOK	<i>Balance your checkbook.</i>	11
DECIDE	<i>Choose the best decision from your list of alternatives.</i>	21
LOAN	<i>Calculate payments and interest for mortgages, car loans, etc.</i>	33
MILEAGE	<i>Analyze your car's gasoline usage.</i>	41
STOPWATCH	<i>Your computer can be a sophisticated stopwatch.</i>	49

Section 2—EDUCATIONAL PROGRAMS

To help yourself or others to learn.

ARITHMETIC	<i>Math drills for school-aged children.</i>	55
FLASHCARD	<i>Create your own flashcards, then practice.</i>	63
METRIC	<i>Learn the metric system.</i>	73
NUMBERS	<i>Help pre-school children to learn numbers.</i>	81
TACHIST	<i>Increase your reading speed with this tachistoscope.</i>	87
VOCAB	<i>Expand your vocabulary.</i>	95

Section 3—GAME PROGRAMS

Match wits with the computer or a friend.

DECODE	<i>Figure out the computer's secret code.</i>	105
GROAN	<i>This dice game will make you do just that.</i>	113
JOT	<i>Challenge the computer to this word and logic game.</i>	121
OBSTACLE	<i>Play a friend at this arcade-like game.</i>	131
ROADRACE	<i>Try to keep the car on the road.</i>	139
WARI	<i>Attempt to beat the computer at this ancient African skill game.</i>	147

Section 4—GRAPHICS DISPLAY PROGRAMS

Dazzling visual diversions.

KALEIDO	<i>A kaleidoscope with eight point symmetry.</i>	159
SPARKLE	<i>Hypnotic sparkling patterns.</i>	165
SQUARES	<i>Overlaying concentric squares.</i>	169
WALLOONS	<i>A classic from the PET Playhouse.</i>	173

Section 5—MATHEMATICS PROGRAMS

For math, engineering, and statistical uses.

CURVE	<i>Perform least-squares curve fitting.</i>	183
DIFFEQN	<i>Solve ordinary differential equations.</i>	193
GRAPH	<i>Display a simple graph of a function.</i>	203
INTEGRATE	<i>Determine the area under a curve.</i>	213
SIMEQN	<i>Solve simultaneous linear equations.</i>	221
STATS	<i>Perform standard "statistics of population" calculations.</i>	227

Section 6—MISCELLANEOUS PROGRAMS

Short programs that do interesting things.

BIRTHDAY	<i>What are the odds of identical birthdays in a group of people?</i>	243
PI	<i>Calculate an approximation of pi.</i>	247
POWERS	<i>Calculate powers of integers—up to 250 digits long.</i>	253
PYTHAG	<i>Generate Pythagorean triplets ($a^2 + b^2 = c^2$).</i>	259
Appendix 1—MEMORY USAGE		263
Bibliography		265

Section 1

Applications Programs

INTRODUCTION TO APPLICATIONS PROGRAMS

Good practical applications are certainly a prime use of personal computers. There are a myriad of ways the PET can help us to do useful work. Here are six programs for use around the home or business.

Financial considerations are always important. LOAN will calculate interest, payment schedules etc. for mortgages, car loans, or any such business loan. Do you ever have trouble balancing your checkbook(s)? CHECKBOOK will enable you to rectify your monthly statements and help you find the cause of any errors.

Fuel usage is a constant concern for those of us who drive. MILEAGE will determine and keep track of a motor vehicle's general operating efficiency.

By no means is the PET restricted to numerical type applications. STOPWATCH will turn your computer into a precise sophisticated stopwatch with a variety of uses.

Often we are faced with difficult decisions. DECIDE transforms the PET into a trusty advisor. Help will be at hand for any decision involving the selection of one alternative from several choices.

Before anything else, you might want to consult BIORHYTHM each day. Some major airlines, and other industries, are placing credence on biorhythm theory. If you agree, or "just in case," simply turn on your PET and load this program.

BIORHYTHM

PURPOSE

Did you ever have one of those days when nothing seemed to go right? All of us seem to have days when we are clumsy, feel depressed, or just cannot seem to force ourselves to concentrate as well as usual. Sometimes we know why this occurs. It may result from the onset of a cold or because of an argument with a relative. Sometimes, however, we find no such reason. Why can't we perform up to par on some of those days when nothing is known to be wrong?

Biorhythm theory says that all of us have cycles, beginning with the moment of birth, that influence our physical, emotional, and intellectual states. We will not go into a lot of detail about how biorhythm theory was developed (your local library probably has some books about this if you want to find out more), but we will summarize how it supposedly affects you.

The physical cycle is twenty-three days long. For the first 11½ days, you are in the positive half of the cycle. This means you should have a feeling of physical well-being, strength, and endurance. During the second 11½ days, you are in the negative half of the cycle. This results in less endurance and a tendency toward a general feeling of fatigue.

The emotional cycle lasts for twenty-eight days. During the positive half (the first fourteen days), you should feel more cheerful, optimistic, and cooperative. During the negative half, you will tend to be more moody, pessimistic, and irritable.

The third cycle is the intellectual cycle, which lasts for thirty-three days. The first half is a period in which you should

have greater success in learning new material and pursuing creative, intellectual activities. During the second half, you are supposedly better off reviewing old material rather than attempting to learn difficult new concepts.

The ups and downs of these cycles are relative to each individual. For example, if you are a very self-controlled, unemotional person to begin with, your emotional highs and lows may not be very noticeable. Similarly, your physical and intellectual fluctuations depend upon your physical condition and intellectual capacity.

The day that any of these three cycles changes from the plus side to the minus side (or vice versa) is called a "critical day." Biorhythm theory says that you are more accident-prone on critical days in your physical or emotional cycles. Critical days in the intellectual cycle aren't considered as dangerous, but if they coincide with a critical day in one of the other cycles, the potential problem can increase. As you might expect, a triple critical day is one on which you are recommended to be especially careful.

Please note that there is quite a bit of controversy about biorhythms. Most scientists feel that there is not nearly enough evidence to conclude that biorhythms can tell you anything meaningful. Others believe that biorhythm cycles exist, but that they are not as simple and inflexible as the 23, 28, and 33 day cycles mentioned here.

Whether biorhythms are good, bad, true, false, or anything else is not our concern here. We are just presenting the idea to you as an interesting theory that you can investigate with the help of your PET computer.

HOW TO USE IT

The program first asks for the birth date of the person whose biorhythm cycles are to be charted. You provide the month and day as you might expect. For the year, you only need to enter the last two digits if it is between 1900 and 1999. Otherwise, enter all four digits.

Next the program asks you for the start date for the biorhythm chart. Enter it in the same way. Of course, this date cannot be earlier than the birth date.

After a delay of about a second, the program clears the screen and begins plotting the biorhythm chart, one day at a time. The

left side of the screen displays the date, while the right side displays the chart. The left half of the chart is the “down” (negative) side of each cycle. The right half is the “up” (positive) side. The center line shows the critical days when you are at a zero point (neither positive or negative).

Each of the three curves is plotted with an identifying letter—P for physical, E for emotional, and I for intellectual. When the curves cross, an asterisk is displayed instead of either of the two (or three) letters.

Eighteen days of the chart are displayed on one screen, and then the program waits for you to press a key. If you press the E key, the current chart ends and the program starts over again. If you press the **SPACE** key (or any other key except **STOP** or **SHIFT**), the program clears the screen and displays the next eighteen days of the chart.

The program will allow you to enter dates from the year 100 A.D. and on. We make no guarantees about any extreme future dates, however, such as entering a year greater than 3000. We sincerely hope that these limitations do not prove to be too confining for you.

SAMPLE RUN

The operator enters his or her birth date and the date for the beginning of the chart

The program responds with the first 18 days of the operator's biorhythm chart, then waits for a key to be pressed.

EASY CHANGES

1. Want to see the number of days between any two dates?
Insert this line:

```
305 PRINT "DAYS ="; N: END
```

Then enter the earlier date as the birth date, and the later date as the start date for the chart. This will cause the program to display the difference in days and then end.

2. To alter the number of days of the chart shown on each screen, alter the 18 in line 360. You might prefer 14, for example.

MAIN ROUTINES

- 120 - 140 Initializes variables. Displays titles.
- 150 - 180 Asks for birth date and converts to Julian date format (i.e., the number of days since January 1, 4713 B.C.
- 190 - 220 Asks for start date for chart and converts to Julian date format.
- 230 - 260 Checks that chart date is not sooner than birth date.

270	Delays about one second before displaying chart.
280	Displays heading at top of screen.
300	Determines number of days between birth date and current chart date.
310 - 330	Plots points in L\$ string for each of the three cycles.
340	Converts Julian date back into month-day-year format.
350	Displays one line on the chart.
360 - 400	Adds one to chart date. Checks to see if the screen is full.
500 - 580	Subroutine to ask operator for month, day, and year. Edits replies.
600 - 670	Subroutine to convert month, day, and year into Julian date format.
700 - 750	Subroutine to clear screen and display headings.
800 - 810	Subroutine to calculate remainder R of N/V.
850 - 990	Subroutine to plot a point in L\$ based on V and R.
1000 - 1140	Subroutine to convert Julian date JC back into month-day-year format.
1200 - 1230	Subroutine to create a string of 31 horizontal graphics characters.

MAIN VARIABLES

L	Counter of number of lines on screen.
Z	Constant used in integer truncation.
T	Number of characters on one side of the center of the chart.
P	Pi.
JB	Birth date in Julian format.
JD	Julian date calculated in subroutine.
JC	Chart start date in Julian format.
J	Loop and work variable.
N	Number of days between birth and current chart date.
V	Number of days in present biorhythm cycle (23, 28, or 33).
C\$	String with date in month/day/year format.
L\$	String with one line of the biorhythm chart.
R\$	Reply from operator after screen fills up.
M	Month (1 - 12)
D	Day (1 - 31)
Y	Year (100 or greater)

W, B	Work variables.
R	Remainder of N/V (number of days into cycle).
U\$	String of 31 horizontal graphics characters.
A\$	Work variable.

SUGGESTED PROJECTS

Investigate the biorhythms of some famous historical or athletic personalities. For example, are track and field athletes usually in the positive side of the physical cycle on the days that they set world records? Where was Lincoln in his emotional and intellectual cycles when he wrote "The Gettysburg Address"? Do a significant percentage of accidents befall people on critical days?

CHECKBOOK

PURPOSE

Many people consider the monthly ritual of balancing the checkbook to be an irritating and error-prone activity. Some people get confused and simply give up after the first try, while others give up the first time they cannot reconcile the bank statement with the checkbook. Fortunately, you have an advantage—your computer. This program takes you through the necessary steps to balance your checkbook, doing the arithmetic for you, of course.

HOW TO USE IT

The program starts off by giving you instructions about how to verify that the amount of each check and deposit are the same on the statement as they are in your checkbook. Sometimes the bank will make an error in reading the amount that you wrote on a check (especially if your handwriting is not too clear), and sometimes you will copy the amount incorrectly into your checkbook. While you are comparing these figures, make a check mark in your checkbook next to each check and deposit listed on the statement. A good system is to alternate the marks you use each month (maybe an “x” one month and a check mark the next) so you can easily see which checks and deposits came through on which statement.

Next, the program asks for the ending balance shown on the bank statement. You are then asked for the *check number* (not the amount) of the most recent check shown on the statement.

This will generally be the highest numbered check the bank has processed, unless you like to write checks out of sequence. Your account balance after this most recent check will be reconciled with the statement balance, so that is what the program asks for next—your checkbook balance after the most recent check.

The program must compensate for any differences between what your checkbook has in it prior to the most recent check and what the statement has on it. First, if you have any deposits that are not shown on the statement before the most recent check, you must enter them. Generally, there are none, so you just enter “END.”

Next you have to enter the amounts of any checks that have not yet “cleared” the bank and that are prior to the most recent check. Look in your checkbook for any checks that do not have your check mark next to them. Remember that some of these could be several months old.

Next you enter the amount of any service charges or debit memos that are on the statement, but which have not been shown in your checkbook prior to the most recent check. Typically, this is just a monthly service charge, but there might also be charges for printing new checks for you or some other adjustment that takes money away from you. Credit memos (which give money back to you) are not entered until later. Be sure to make an entry in your checkbook for any of these adjustments so that next month’s statement will balance.

Finally, you are asked for any recent deposits or credit memos that were *not* entered in your checkbook prior to the most recent check, but that *are* listed on the bank statement. It is not unusual to have one or two of these, since deposits are generally processed by banks sooner than checks.

Now comes the moment of truth. The program tells you whether or not you are in balance and displays the totals. If so, pack things up until next month’s statement arrives.

If not, you have to figure out what is wrong. You have seven options of what to do next which allow you to review the numbers you entered in case of a typing error. If you find an error, go back to the beginning and try again. Of course, if it is a simple error that precisely accounts for the amount by which you are out of balance, there is no need to go through the whole thing again.

If you entered everything correctly, the most likely cause of the out of balance condition is an arithmetic error in your checkbook. Look for errors in your addition and subtraction, with subtraction being the most likely culprit. This is especially likely if the amount of the error is a nice even number like one dollar or ten cents.

Another common error is accidentally adding the amount of a check in your checkbook instead of subtracting it. If you did this, your error will be twice the amount of the check (which makes it easy to find).

If this still does not explain the error, check to be sure you subtracted *last* month's service charge when you balanced your checkbook with the previous statement. And, of course, if you did not balance your checkbook last month, you cannot expect it to come out right this month.

The program has limitations of how many entries you can make in each category (checks outstanding, deposits outstanding, etc.), but these can be changed easily. See "Easy Changes" below.

NOTE: SEE DISCLAIMER IN FRONT PART OF BOOK.

SAMPLE RUN

CHECKBOOK BALANCER

FIRST, COMPARE THE BANK STATEMENT
WITH YOUR CHECKBOOK.

MAKE SURE THE STATEMENT AND THE
CHECKBOOK SHOW THE SAME FIGURES
FOR EACH CHECK AND DEPOSIT.

MAKE A MARK IN THE CHECKBOOK NEXT TO
EACH CHECK AND DEPOSIT LISTED
ON THE STATEMENT.

WHAT'S THE ENDING BALANCE SHOWN
ON THE STATEMENT?
? 520.16

NOW FIND THE MOST RECENT CHECK THAT
IS SHOWN ON THE BANK STATEMENT.

WHAT IS THE CHECK NUMBER OF
THIS CHECK? 1652

WHAT BALANCE DOES YOUR CHECKBOOK
SHOW AFTER CHECK NO. 1652
? 480.12

ENTER THE AMOUNT OF EACH DEPOSIT
THAT IS SHOWN IN YOUR CHECKBOOK
PRIOR TO CHECK NO. 1652
BUT IS NOT ON THE STATEMENT.

WHEN NO MORE, SAY 'END'
? END

TOTAL = 0

NOW ENTER THE AMOUNTS OF ANY CHECKS
THAT ARE IN YOUR CHECKBOOK PRIOR
TO CHECK 1652 BUT THAT
HAVE NOT BEEN SHOWN ON A BANK
STATEMENT YET.

WHEN NO MORE, SAY 'END'
? 35.04
? 10
? END

TOTAL = 45.04

NOW ENTER THE AMOUNTS OF ANY
SERVICE CHARGES OR DEBIT MEMOS.

WHEN NO MORE, SAY 'END'
? 2.35
? 2.65
? END

TOTAL = 5

ENTER THE AMOUNT OF EACH DEPOSIT
THAT IS SHOWN IN YOUR CHECKBOOK

AFTER CHECK NO. 1652 THAT IS
ALSO LISTED ON THE STATEMENT.

WHEN NO MORE, SAY 'END'
? END

TOTAL = 0

CONGRATULATIONS! IT BALANCES.

STATEMENT BALANCE + DEPOSITS OUTSTANDING

+ SERVICE CHARGES = 525.16

CHECKBOOK BALANCE + CHECKS OUTSTANDING
+ RECENT DEPOSITS = 525.16

DIFFERENCE = 0

NEXT ACTION:

- 1 - LIST CHECKS OUTSTANDING
- 2 - LIST DEPOSITS OUTSTANDING
- 3 - LIST SERVICE CHARGES
- 4 - START OVER
- 5 - END PROGRAM
- 6 - DISPLAY BALANCING INFO
- 7 - LIST DEPOSITS AFTER LAST CHECK

? 5

READY.

EASY CHANGES

Change the limitations of how many entries you can make in each category. Line 150 establishes these limits. If you have more than ten checks outstanding at some time, change the value of MC to 20, for example. The other three variables can also be changed if you anticipate needing more than five entries. They are: the number of deposits outstanding (MD), the number of service charges and debit memos (MS), and the number of recent deposits and credit memos (MR).

MAIN ROUTINES

- | | |
|-----------|--|
| 120 - 290 | Initializes variables and displays first instructions. |
| 300 - 370 | Gets most recent check number. |
| 380 - 410 | Gets checkbook balance after most recent check number. |
| 420 - 545 | Gets outstanding deposits. |
| 550 - 690 | Gets outstanding checks. |

700 - 800	Gets service charges and debit memos.
805	Gets recent deposits and credit memos.
810 - 920	Does balancing calculation. Displays it.
930 - 1050	Asks for next action. Goes to appropriate subroutine.
1100 - 1130	Subroutine to display checks outstanding.
1200 - 1230	Subroutine to display deposits outstanding.
1300 - 1330	Subroutine to display service charges and debit memos.
1400 - 1410	Clears variables and restarts program.
1500	Ends the program.
1700 - 1730	Subroutine to display recent deposits.
2000 - 2140	Subroutine to get recent deposits.

MAIN VARIABLES

MC	Maximum number of checks outstanding.
MD	Maximum number of deposits outstanding.
MS	Maximum number of service charges, debit memos.
MR	Maximum number of recent deposits, credit memos.
C	Array for checks outstanding.
D	Array for deposits outstanding.
S	Array for service charges and debit memos.
R	Array for recent deposits and credit memos.
TC	Total of checks outstanding.
TD	Total of deposits outstanding.
TS	Total of service charges and debit memos.
TR	Total of recent deposits and credit memos.
NC	Number of checks outstanding.
ND	Number of deposits outstanding.
NS	Number of service charges and debit memos.
NR	Number of recent deposits and credit memos.
E\$	Error message.
SB	Statement balance.
LC	Number of last check on statement.
CB	Checkbook balance after last check on statement.
R\$	Reply from operator.
W	Amount by which checkbook is out of balance.
R	Numeric value of reply for next action.

SUGGESTED PROJECTS

1. Add more informative messages and a more complete introduction to make the program a tutorial for someone who has never balanced a checkbook before.
2. Allow the operator to modify any entries that have been discovered to be in error. This could be done by adding another option to the "NEXT ACTION" list, which would then ask the operator which category to change. This would allow the operator to correct an error without having to re-enter everything from the beginning.
3. If the checkbook is out of balance, have the program do an analysis (as suggested in the "How To Use It" section) and suggest the most likely errors that might have caused the condition.
4. Allow the operator to find arithmetic errors in the checkbook. Ask for the starting balance, then ask for each check or deposit amount. Add or subtract, depending on which type the operator indicates. Display the new balance after each entry so the operator can compare with the checkbook entry.

DECIDE

PURPOSE

“Decisions, decisions!” How many times have you uttered this lament when confronted by a difficult choice? Wouldn’t a trusty advisor be helpful on such occasions? Well, you now have one -your PET computer of course.

This program can help you make decisions involving the selection of one alternative from several choices. It works by prying relevant information from you and then organizing it in a meaningful, quantitative manner. Your best choice will be indicated and all of the possibilities given a relative rating.

You can use the program for a wide variety of decisions. It can help with things like choosing the best stereo system, saying yes or no to a job or business offer, or selecting the best course of action for the future. Everything is personalized to your individual decision.

HOW TO USE IT

The first thing the program does is ask you to categorize the decision at hand into one of these three categories:

- 1) Choosing an item (or thing),
- 2) Choosing a course of action, or
- 3) Making a yes or no decision.

You simply press **1**, **2**, or **3** to indicate which type of decision is facing you. (It is not necessary to hit the **RETURN** key.) If you are choosing an item, you will be asked what type of item it is.

If the decision is either of the first two types, you must next enter a list of all the possibilities under consideration. A question mark will prompt you for each one. When the list is complete, type "END" in response to the last question mark. You must, of course, enter at least two possibilities. (We hope you don't have trouble making decisions from only one possibility!) After the list is finished, it will be re-displayed so that you can verify that it is correct. If not, you must re-enter it.

Now you must think of the different factors that are important to you in making your decision. For example, location, cost, and quality of education might govern the decision of which college to attend. For a refrigerator purchase, the factors might be things like price, size, reliability, and warranty. In any case, you will be prompted for your list with a succession of question marks. Each factor is to be entered one at a time with the word "END" used to terminate the list. When complete, the list will be re-displayed. You must now decide which single factor is the most important and input its number. (You can enter 0 if you wish to change the list of factors.)

The program now asks you to rate the importance of each of the other factors relative to the most important one. This is done by first assigning a value of 10 to the main factor. Then you must assign a value from 0 - 10 to each of the other factors. These numbers reflect your assessment of each factor's relative importance as compared to the main one. A value of 10 means it is just as important; lesser values indicate how much less importance you place on it.

Now you must rate the decision possibilities with respect to each of the importance factors. Each importance factor will be treated separately. Considering *only* that importance factor, you must rate how each decision possibility stacks up. The program first assigns a value of 10 to one of the decision possibilities. Then you must assign a relative number (lower, higher, or equal to 10) to each of the other decision possibilities.

An example might alleviate possible confusion here. Suppose you are trying to decide whether to get a dog, cat, or canary for a pet. Affection is one of your importance factors. The program assigns a value of 10 to the cat. Considering *only* affection, you might assign a value of 20 to the dog and 6.5 to the canary. This means *you* consider a dog twice as affectionate as a cat but a canary only about two thirds as affectionate as a cat. (No

slighting of bird lovers is intended here, of course. Your actual ratings may be entirely different.)

Armed with all this information, the program will now determine which choice seems best for you. The various possibilities are listed in order of ranking. Alongside each one is a relative rating with the best choice being normalized to a value of 100.

Of course, DECIDE should not be used as a substitute for good, clear thinking. However, it can often provide valuable insights. You might find one alternative coming out surprisingly low or high. A trend may become obvious when the program is re-run with improved data. At least, it may help you think about decisions systematically and honestly.

SAMPLE RUN

DECIDE

I CAN HELP YOU MAKE A DECISION. ALL
I NEED TO DO IS ASK SOME QUESTIONS AND
THEN ANALYZE THE INFORMATION YOU GIVE.

WHICH OF THESE BEST DESCRIBES THE TYPE
OF DECISION FACING YOU?

- 1) CHOOSING AN ITEM FROM VARIOUS
ALTERNATIVES.
- 2) CHOOSING A COURSE OF ACTION FROM
VARIOUS ALTERNATIVES.
- 3) MAKING A 'YES' OR 'NO' DECISION.

WHICH ONE (1, 2, OR 3)? 1

WHAT TYPE OF ITEM MUST YOU DECIDE UPON
? VACATION

I NEED TO HAVE A LIST OF EACH
VACATION UNDER CONSIDERATION.

INPUT THEM ONE AT A TIME
IN RESPONSE TO EACH QUESTION MARK.

THE ORDER IN WHICH YOU INPUT THEM
HAS NO PARTICULAR SIGNIFICANCE.

TYPE THE WORD 'END' TO INDICATE
THAT THE WHOLE LIST HAS BEEN ENTERED.

? MOUNTAIN CAMPING
 ? AFRICAN SAFARI
 ? TRIP TO WASHINGTON D.C.
 ? END

O.K. HERE'S THE LIST YOU'VE GIVEN ME:

- 1) MOUNTAIN CAMPING
- 2) AFRICAN SAFARI
- 3) TRIP TO WASHINGTON D.C.

IS THIS LIST CORRECT (Y OR N) ? YES

NOW, THINK OF THE DIFFERENT FACTORS
 THAT ARE IMPORTANT TO YOU IN CHOOSING
 THE BEST VACATION.

INPUT THEM ONE AT A TIME IN RESPONSE
 TO EACH QUESTION MARK.

TYPE THE WORD 'END' TO TERMINATE
 THE LIST.

? RELAXATION
 ? AFFORDABILITY
 ? CHANGE OF PACE
 ? END

HERE'S THE LIST OF FACTORS YOU GAVE ME:

- 1) RELAXATION
- 2) AFFORDABILITY
- 3) CHANGE OF PACE

DECIDE WHICH FACTOR ON THE LIST IS
 THE MOST IMPORTANT AND INPUT ITS NUMBER.

(TYPE Ø IF THE LIST NEEDS CHANGING.)

? 2

NOW LET'S SUPPOSE WE HAVE A SCALE OF
 IMPORTANCE RANGING FROM Ø-1Ø.

WE'LL GIVE AFFORDABILITY A
 VALUE OF 1Ø SINCE AFFORDABILITY
 WAS RATED THE MOST IMPORTANT.

ON THIS SCALE, WHAT VALUE OF
 IMPORTANCE WOULD THE OTHER FACTORS HAVE?

RELAXATION

? 5.5

CHANGE OF PACE

? 9

EACH VACATION
MUST NOW BE COMPARED WITH RESPECT TO
EACH IMPORTANCE FACTOR.

WE'LL CONSIDER EACH FACTOR
SEPARATELY AND THEN RATE
EACH VACATION IN TERMS
OF THAT FACTOR ONLY.

LET'S GIVE MOUNTAIN CAMPING
A VALUE OF 10 ON EVERY SCALE.

THEN EVERY OTHER VACATION
WILL BE ASSIGNED A VALUE HIGHER OR
LOWER THAN 10. THIS VALUE DEPENDS ON
HOW MUCH YOU THINK IT IS BETTER OR
WORSE THAN MOUNTAIN CAMPING

CONSIDERING ONLY RELAXATION AND
ASSIGNING 10 TO MOUNTAIN CAMPING ;
WHAT VALUE WOULD YOU ASSIGN TO

AFRICAN SAFARI? 3

TRIP TO WASHINGTON D.C.? 9

CONSIDERING ONLY AFFORDABILITY AND
ASSIGNING 10 TO MOUNTAIN CAMPING ;
WHAT VALUE WOULD YOU ASSIGN TO

AFRICAN SAFARI? 1

TRIP TO WASHINGTON D.C.? 8

CONSIDERING ONLY CHANGE OF PACE AND
ASSIGNING 10 TO MOUNTAIN CAMPING ;
WHAT VALUE WOULD YOU ASSIGN TO

AFRICAN SAFARI? 60

TRIP TO WASHINGTON D.C.? 25

TRIP TO WASHINGTON D.C. COMES OUT BEST
BUT IT'S VERY CLOSE.

HERE IS THE FINAL LIST IN ORDER.

TRIP TO WASHINGTON D.C. HAS BEEN

GIVEN A VALUE OF 100 AND THE OTHERS
RATED ACCORDINGLY.

```

-----
100      TRIP TO WASHINGTON D.C.
98.6587184 MOUNTAIN CAMPING
78.8375559 AFRICAN SAFARI

```

READY.

PROGRAM LISTING

READY.

```

EASY CHANGES

1. The word "END" is used to flag the termination of various input lists. If you wish to use something else (because of conflicts with items on the list), change the definition of E\$ in line 180. For example, to use the word "DONE," change line 180 to

180 E\$="DONE"

2. Line 2100 contains a timing delay used regularly in the program. If things seem to change too fast, you can make the number 2500 larger. Try

2100 FOR J=1 TO 5000:NEXT J:RETURN

3. The program can currently accept up to nine decision alternatives and/or nine importance factors. If you need more, increase the dimensioning in line 160. Each dimension value is one more than the number the program will actually allow. Thus, to use 14 values, line 160 should be

```
160 DIM L$(15),F$(15),V(15),C(15,15),D(15),Z(15)
```

MAIN ROUTINES

160 - 190	Initializes and dimensions variables.
200 - 350	Determines category of decision.
400 - 490	Gets or sets T\$.
500 - 730	Gets list of possible alternatives from user.
750 - 950	Gets list of importance factors from user.
1000 - 1110	User rates each importance factor.
1200 - 1470	User rates the decision alternatives with respect to each importance factor.
1500 - 1570	Evaluates the various alternatives.
1600 - 1630	Sorts alternatives into their relative ranking.
1700 - 1860	Displays results.
2000 - 2010	Subroutine to clear screen and display header.
2100	Time wasting subroutine.

MAIN VARIABLES

NI	Number of decision alternatives.
L\$	String array of the decision alternatives.
NF	Number of importance factors.
F\$	String array of the importance factors.
V	Array of the relative values of each importance factor.
A	Index number of most important factor.
C	Array of relative values of each alternative with respect to each importance factor.
T	Decision category (1=item, 2=course of action, 3=yes or no).
T\$	String name of decision category.
E\$	String to signal the end of an input data list.
J,K	Loop indices.
R\$	User reply string.
Q,N1,N2	Work variables.

D	Array of each alternative's value.
MX	Maximum value of all alternatives.
DF	Rating difference between best two alternatives.
Z	Array of the relative rankings of each alternative.

SUGGESTED PROJECTS

1. Allow the user to review his numerical input and modify it if desired.
2. Insights into a decision can often be gained by a sensitivity analysis. This involves running the program a number of times for the same decision. Each time, one input value is changed (usually the one you are least confident about). By seeing how the results change, you can determine which factors are the most important. Currently, this requires a complete re-running of the program each time. Modify the program to allow a change of input after the regular output is produced. Then recalculate the results based on the new values. (Note that many input arrays are clobbered once all the input is given. This modification will require saving the original input in new arrays so that it can be reviewed later.)

LOAN

PURPOSE

One of the most frustrating things about borrowing money from a bank (or credit union or Savings and Loan) is that it's not easy to fully evaluate your options. When you are borrowing from a credit union to buy a new car, you might have the choice of a thirty-six or a forty-eight month repayment period. When buying a house, you can sometimes get a slightly lower interest rate for your loan if you can come up with a larger down payment. Which option is best for you? How will the monthly payment be affected? Will there be much difference in how fast the principal of the loan decreases; How much of each payment will be for interest, which is tax-deductible?

You need to know the answers to all these questions to make the best decision. This program gives you the information you need.

HOW TO USE IT

The program first asks you the size of the loan you are considering. Only whole dollar amounts are allowed—no pennies. Loans of ten million dollars or more are rejected (you can afford to hire an investment counselor if you want to borrow that much). Then you are asked the yearly interest rate for the loan. Enter this number as a percentage, such as “10.8”. Next, you are asked to give the period of the loan in months. For a five year loan, enter 60. For a thirty year mortgage, enter 360. The program then displays this information for you and calculates

the monthly payment that will cause the loan to be paid off with equal payments each month over the life of the loan.

At this point you have four options. First, you can show a monthly analysis. This displays a month-by-month breakdown, showing the state of the loan after each payment. The four columns of data shown for each month are the payment number (or month number) of the loan, the remaining balance of the loan after that payment, the amount of that payment that was interest, and the accumulated interest paid to date. Sixteen lines of data are displayed on the screen, and then you can either press the **T** key to get the final totals for the loan, or any other key to get the data for the next sixteen months of the loan.

The second option is overriding the monthly payment. It is a common practice with second mortgage loans to make smaller monthly payments each month with a large “balloon” payment as the final payment. You can use this second option to try various monthly payments to see how they affect that big payment at the end. After overriding the monthly payment, you will want to use the first option next to get a monthly analysis and final totals using the new monthly payment.

The third option is to simply start over. You will generally use this option if you are just comparing what the different monthly payments would be for different loan possibilities.

The fourth option ends the program.

By the way, there is a chance that the monthly payment calculated by your lender will differ from the one calculated here by a penny or two. We like to think that this is because we are making a more accurate calculation.

NOTE: SEE DISCLAIMER IN FRONT PART OF BOOK

SAMPLE RUN

The operator enters the three necessary pieces of information about his or her loan.

The program responds with the monthly payment that will pay off the loan with equal payments over its life, then asks the operator what to do next. The operator asks for the monthly analysis.

```

EASY CHANGES

1. The number of lines of data that are displayed on each screen when getting a monthly analysis can be changed by altering the constant 16 in statement 620. You might want only twelve payments shown at a time so you can see a year-by-year analysis.
2. To include the monthly payment in the heading at the top of each screen of the monthly analysis, insert the following line:

```
815 IF FP<>0 THEN PRINT"MONTHLY PAYMENT IS";FP
```

MAIN ROUTINES

120 - 170	Displays title. Gets loan information.
200 - 230	Calculates and displays monthly payment.
250 - 370	Asks for next action. Goes to corresponding routine.
400 - 410	Gets override for monthly payment.
440 - 730	Calculates and displays monthly analysis.
800 - 830	Subroutine to clear screen and display data about the loan at the top.
900 - 970	Subroutine to convert integer amount to fixed-length string with aligned decimal point.
1000 - 1030	Edits loan amount (size and whole dollar).

MAIN VARIABLES

A	Amount of loan.
R	Interest rate (percentage).
N	Length of loan (number of months).
M	Monthly interest rate (not percentage).
W	Work variable.
P	Monthly payment.
FP	First monthly payment.
C	Choice of next action.
B	Remaining balance of loan.
TT	Total interest to date.
TP	Total payments to date.
L	Number of lines of data on screen.
R\$	Reply from operator at keyboard.
J	Work variable for loops.
T	Monthly interest.
B\$	Remaining balance (string format).
T\$	Monthly interest (string format).
TT\$	Total interest to date (string format).
S\$	Work string variable for creating numbers with decimal point alignment.
D\$	Work variable used in building S\$.
K	Work variable used in building S\$.

SUGGESTED PROJECTS

1. Display a more comprehensive analysis of the loan along with the final totals. Show the ratio of total payments to the amount of the loan (TP divided by A), for example.
2. Modify the program to show an analysis of resulting monthly payments for a range of interest rates and/or loan lengths near those provided by the operator. For example, if an interest rate of 9.5 percent was entered, display the monthly payments for 8.5, 9, 9.5, 10, and 10.5 percent.

MILEAGE

PURPOSE

For many of us, automobile operating efficiency is a continual concern. This program can help by keeping track of gasoline consumption, miles driven, and fuel mileage for a motor vehicle. It allows reading and writing data files with the cassette unit. Thus, a master data file may be retained and updated. The program computes mileage (miles per gallon or MPG) obtained after each gasoline fill-up. A running log of all information is maintained. This enables trends in vehicle operation efficiency to be easily checked.

HOW TO USE IT

The program requests the following data from the operator as a record of each gasoline fill-up: date, odometer reading, and number of gallons purchased. The most useful results will be obtained if entries are chronological and complete, with each entry representing a full gasoline fill-up.

In order to use the cassette features, the operator must be able to position the tape correctly for both reading and writing. The simplest way to do this is to only record files at the beginning of a tape. One tape could certainly be used this way, with each file writing over the previous one. However, we suggest alternating between two physical tapes. This will insure a reasonably up-to-date back-up tape in case of any failure.

The program operates from a central command mode. The operator requests branching to any one of five available subrou-

tines. When a subroutine completes execution, control returns to the command mode for any additional requests. A brief description of each subroutine now follows:

1) READ OLD MASTER FILE

This reads previously stored data from the cassette. Any data already in memory is deleted. During the read, the name of the data file and the total number of records read are displayed.

2) INPUT FROM TERMINAL

This allows data records to be entered directly from the terminal. This mode is used to provide additional information after a cassette read and to enter data for the first time. The program will prompt the operator for the required information and then let him verify that it was entered correctly. A response of "F" to the verification request signals that no more data is to be entered.

3) WRITE NEW MASTER FILE

This command causes the current data to be written on cassette. The program requests a name for the file. When later read, this name will be displayed, allowing verification of the correct data file.

4) DISPLAY MILEAGE DATA

This subroutine computes mileage (miles per gallon) from the available data. It formats all information and displays it in tabular form. Numbers are rounded to the nearest tenth so that four columns of information can be displayed on one line. When data fills the screen, the user is prompted to press the **RETURN** key to continue the listing. When all data is displayed, pressing the **RETURN** key will re-enter command mode.

5) TERMINATE PROGRAM

Ends execution and returns the computer to BASIC.

SAMPLE RUN

RUN

MILEAGE

COMMANDS

- 1 - READ OLD MASTER FILE FROM CASSETTE
- 2 - INPUT DATA FROM TERMINAL
- 3 - WRITE NEW MASTER FILE TO CASSETTE

```

EASY CHANGES

1. Changing the value of MR in line 120 alters the maximum number of data records that the program allows. You may need to make MR smaller if you are running out of memory, or larger to accommodate additional data. MR can only be about 15 with a 4K PET. For typical data (such as in the sample run), an 8K PET will allow about 150 data records. To adjust MR, simply change its value in line 120 from its current value of 75 to whatever you choose.
2. Currently, the program will write a maximum of sixty data records during the cassette write operation. This number can be altered by changing the value of MW in line 120 from its

value of sixty to whatever you choose. Only the most recent MW records will be written to tape if MW is less than the number of available records when a cassette write is issued. If the number of available records is less than MW, then all the records will be written. The value of MW should not be larger than the value of MR.

3. If you do not care about seeing the dates, they can be removed easily. This saves a little typing on data entry and also allows more data records in a given amount of memory. To remove this feature, delete line 320 entirely and change line 340 to read

```
340 N=N+1:PRINT:D$(N)="- - - -"
```

MAIN ROUTINES

120 - 130	Dimensioning and variable initialization.
150 - 210	Command mode. Displays available subroutines and branches to the operator's choice.
250 - 270	Reads data from the cassette unit.
300 - 470	Accepts terminal input.
500 - 570	Writes data to the cassette unit.
600 - 780	Calculates mileage and displays all information.
800	Terminates execution.
850 - 900	Displays messages for cassette operation.
920	Delay loop.
940	Rounds numbers to nearest tenth.
960 - 970	Tests for operator response.

MAIN VARIABLES

MW	Maximum number of data records to write.
MR	Maximum number of data records in memory.
N	Current number of data records in memory.
D\$	Array of dates.
D	Array of odometer readings.
G	Array of gallons per fill-up.
M	Array of mileage per fill-up.
R	Command mode input, also pre-rounded numbers sent to the rounding routine.
R\$	Temporary string variable, holds operator's input.
T\$	Data file name used in reading or writing with cassette.

J	Work variable, loop index.
K,L	Loop bounds.
B	Number of blanks used in display formatting.
U	Number of underlines used in display formatting.
Q	String length used in display formatting.
Z	Cassette delay time during writing.

SUGGESTED PROJECTS

1. Calculate and print the average MPG over the whole data file. The total miles driven is $D(N) - D(1)$. The total gallons used is the sum of $G(J)$ for $J=2$ to N . This calculation can be done at the end of the DISPLAY MILEAGE subroutine. Programming should be done between lines 690 and 700.
2. Allow the user the option to write to cassette only the entries since a certain date. Ask which date and search the D\$ array for it. Then set MW to the appropriate number of records to write. These changes are to be made between lines 500 and 510 at the beginning of the subroutine to write on cassette.
3. Add a new command option to verify a data file just written to cassette. It would read the tape and compare it to the data already in memory.
4. Add an option to do statistical calculations over a given subset of the data. The operator inputs a beginning and ending date. He is then shown things like average MPG, total miles driven, total gallons purchased, etc.; all computed only over the range requested.
5. Write a subroutine to graphically display MPG. A bar graph might work well.
6. Add a new parameter in each data record—the cost of each fill-up. Then compute things like the total cost of gasoline, miles/dollar, etc.

STOPWATCH

PURPOSE

If you are only using your PET for making calculations or other “normal” computer work, you are missing out on something. The PET has a very accurate internal timer, which can be very useful. This program uses it in a very obvious way—as a stopwatch. Using a computer as a stopwatch gives you the advantage of leaving the last few timings on the screen for reference while you are making the next timing. Of course, the computer is “smart” enough to allow you to get “lap” times as well as the final time.

HOW TO USE IT

The opening messages from the program show you your two options. Pressing the **S** key causes the stopwatch to start (or restart, if you had already started it). Pressing the **F** key causes the stopwatch program to show you the time since the **S** key was pressed. Pressing the **F** key a second time causes the program to show you both the time since the start and the time since the last **F** was pressed. This lets you see interim or “lap” times.

For example, suppose you want to time a one-mile race that is run as four laps around a quarter-mile track. Before the race begins, start the program running with the **RUN** command. When the starting gun is fired to start the race, press the **S** key. At the end of the first lap around the track, press the **F** key. This causes the program to show the time since the race started.

When the second lap is completed, press the **F** key again. The program will show the time since the start and the time of the second lap. Press the **F** key again when the third and fourth laps are finished to get the time since start and lap times. Of course, the time since start at the end of the fourth lap is the final time of the race, even though the stopwatch keeps running. At that time, you can either press **S** to restart the stopwatch (when the next race begins) or press the **STOP** key to stop the program.

The internal timer of the PET is accurate to one sixtieth ($1/60$) of a second. The program displays the time as though it is accurate to .01 seconds. As a result, the second decimal place is not precise. The actual time is within plus or minus .02 seconds of the time that is shown. Also, because of the computation time required to display each timing, wait at least .4 seconds between consecutive **F** suppressions.

SAMPLE RUN

First the operator presses "**S**" to start the stopwatch. Then, after about one minute and 19 seconds, he or she presses "**F**". After another 41.56 seconds, "**F**" is pressed again.

PROGRAM LISTING

```

100 REM: STOPWATCH
110 REM: COPYRIGHT 1978 BY TOM RUGG AND PHIL FELDMAN
120 PRINT CHR$(147)
130 PRINT TAB(12);"STOPWATCH":PRINT:PRINT
140 PRINT" S = START OR RESTART"
150 PRINT" F = FINISH (INTERIM OR FINAL)"
160 PRINT:PRINT"? ";
170 GET R$:IF R$="" THEN 170
180 W=TI:PRINT R$
190 IF R$="S" THEN 300
200 IF R$="F" THEN 400
210 GOTO 170
300 L=W:S=W:PRINT"STARTED"
310 GOTO 160
400 J=W-S:GOSUB 500
410 PRINT"SINCE START =" ;R$
420 IF S=L THEN L=W:GOTO 160
430 J=W-L:GOSUB 500
440 PRINT"SINCE LAST 'F' =" ;R$
450 L=W:GOTO 160
500 J=J/60:J=INT(100*J):J=J/100:R$=""
510 IF J>60 THEN 530
520 R$=R$+STR$(J)+" SECONDS":RETURN
530 K=INT(J/60):J=J-(K*60):J=INT(100*J):J=J/100
540 R$=STR$(K)+" MINUTES," :GOTO 520

```

EASY CHANGES

1. To allow *any* key to act like an F (except S), change line 200 to read
200 GOTO 400
2. To always display the time in seconds (instead of minutes and seconds when the time is greater than 60 seconds), delete line 510.
3. To eliminate blank lines on the screen (thus allowing more timings to be retained on the screen), eliminate the first PRINT and colon on line 160.
4. To display the time to the nearest tenth of a second (instead of the nearest hundredth), change the four constant values of 100 in lines 500 and 530 to 10.

MAIN ROUTINES

120 - 150	Displays the title and two options.
160 - 170	Displays question mark and waits for a key to be pressed.
180 - 210	Saves time of key suppression. Checks which key was pressed.
300 - 310	Saves starting time and displays STARTED.
400 - 450	Displays total and lap times.
500 - 540	Subroutine to convert "jiffies" in J into minutes and seconds in R\$.

MAIN VARIABLES

R\$	Keyboard character pressed by operator. Also used when displaying minutes and seconds as a string.
W	Work variable for saving current time.
L	Time that last S or F was pressed.
S	Starting time.
J	Elapsed time (in jiffies) to be displayed.
K	Number of minutes to be displayed when elapsed time is greater than 60 seconds.

SUGGESTED PROJECTS

1. Instead of displaying only the last lap time, display the last two or three lap times. Or, display *all* lap times since the start by saving each time in an array. Allow for at least twenty entries.
2. Allow for the possibility of the time automatically resetting to zero during a timing (by passing midnight or 24 hours since the PET was turned on). Add 24 hours worth of jiffies to W if W is less than S.

Section 2

Educational Programs

INTRODUCTION TO EDUCATION PROGRAMS

Education is one area where computers are certain to have more and more impact. Though a computer cannot completely replace a human teacher, the machine does have certain advantages. It is ready anytime you are, allows you to go at your own pace, handles rote drill effortlessly, and is devoid of any personality conflicts.

With a good software library, the PET can be a valuable learning center in the school or at home. Here are six programs to get you started.

Mathematics is certainly a “natural” subject for computers. NUMBERS is designed for pre-school children. While familiarizing youngsters with computers, it provides an entertaining way for them to learn numbers and elementary counting. ARITHMETIC is aimed at older, grade school students. It provides drill in various kinds of math problems. The child can adjust the difficulty factors, allowing the program to be useful for several years.

By no means is the PET restricted to mathematical disciplines. We include two programs designed to improve your word skills. VOCAB will help you expand your vocabulary. TACHIST turns the PET into a reading clinic, helping you to improve your reading speed.

Do you have trouble familiarizing yourself with the increasingly prevalent metric system? METRIC is the answer.

Need help learning a certain subject? FLASHCARD allows you to create your own “computer flashcards.” Then you can drill yourself until you get it right.

ARITHMETIC

PURPOSE

ARITHMETIC provides mathematics drills for grade school children. The student can request problems in addition, subtraction, or multiplication from the program. Also, he or she may ask that the problems be easy, medium, or hard. The program should be useful to a child over an extended period of time. He can progress naturally to a harder category of problems when he begins to regularly perform well at one level. The difficulty and types of problems encompass those normally encountered by school children between the ages of six and ten.

The problems are constructed randomly within the constraints imposed by the degree of difficulty selected. This gives the student fresh practice each time the program is used. After entering answers, he is told whether he was right or wrong. The correct answers are also displayed.

HOW TO USE IT

To begin, the student must indicate what type of problem he wishes to do. The program requests an input of 1, 2, or 3 to indicate addition, subtraction, or multiplication, respectively. It then asks whether easy, medium, or hard problems are desired. Again an input of 1, 2, or 3 is required.

Now the screen will clear and five problems of the desired type will be displayed. The user now begins to enter his answers to each problem.

A question mark is used to prompt the user for each digit of the answer, one digit at a time. This is done moving right to left, the way arithmetic problems are naturally solved.

To start each problem, the question mark will appear in the spot for the rightmost (or units column) digit of the answer. When the key for a digit from 0 - 9 is pressed, that digit will replace the question mark on the screen. The question mark moves to the immediate left waiting for a digit for the "tens" column.

Digits are entered in this right to left manner until the complete answer has been input. Then the **RETURN** key must be pressed. This will end the answer to the current problem and move the question mark to begin the answer for the next question.

If the **RETURN** key is pressed to begin a problem, an answer of zero is assumed intended. No problems created by this program have answers of more than three digits. If a four-digit answer is given, the program will accept the answer, but then go immediately to the next problem. Answers to the problems are never negative.

The program will display the correct answers to the five problems on the screen after the student has entered his five answers. The message "RIGHT!" or "WRONG!" will also be displayed below each problem.

Then the message "HIT ANY KEY TO CONTINUE" will be displayed. After the key is pressed, a new set of five problems of the same type will be presented.

This continues until twenty problems have been worked. Before ending, the program shows what the student's performance has been. This is expressed as the number of problems solved correctly and also as the percentage of problems solved correctly.

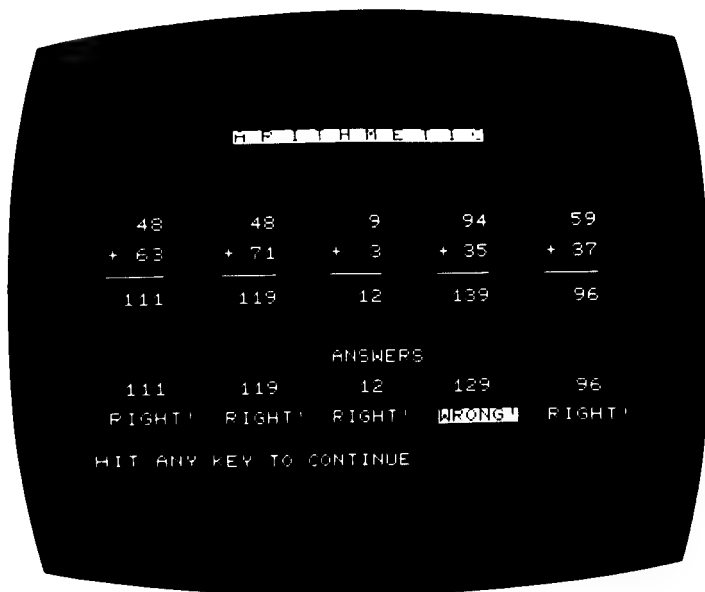

SAMPLE RUN

The operator chooses to do hard addition problems.

The initial set of 5 problems is presented. With a question mark, the program prompts the operator for the answer to the first problem.

The operator has entered his or her five answers. The program displays the correct answers and indicates whether or not each problem was solved correctly. The program waits for the operator to hit any key in order to continue with the next set of five problems.

```

EASY CHANGES

1. The program currently does twenty problems per session. You can change this number by altering the variable NP in line 170. For example,

170 NP=10

will cause the program to do only ten problems per session. The value of NP should be kept a positive multiple of five.

2. Zero is currently allowed as a possible problem operand. If you do not wish to allow this, change lines 940 and 950 to read as follows:

940 H=9:L=1:RETURN

950 H=99:L=1:RETURN

MAIN ROUTINES

150 - 180	Initializes constants, displays header.
200 - 330	Asks operator for type of problems desired.
350 - 450	Sets A, B, C arrays, clears screen.
600 - 730	Mainline routine—displays problems, gets operator's answers, displays correct answers and user's performance.
800 - 870	Subroutine to get and display user's answers.
900	Subroutine to poke byte P into screen position X, Y.
910	Subroutine to clear screen and display title.
920 - 930	Subroutine to set B, C arrays.
940 - 960	Subroutine to set L, H.
1000 - 1030	Subroutine to calculate A array from B, C arrays.
1100 - 1170	Subroutine to display problems.
1200 - 1210	Subroutine to move cursor to screen position X, Y.
1300 - 1310	Subroutine to move cursor CU lines down and CL spaces left.
1400 - 1440	Subroutine to display the correct answers.
1500 - 1540	Subroutine to display operator's performance.

MAIN VARIABLES

NP	Number of problems to do in the session.
ND	Number of problems done.
NR	Number of correct answers given.
C,B,A	Arrays of top operand, bottom operand, and correct answer to each problem.
N	Operator's answer to current problem.
G	Array of operator's answers.
T	Type of problems requested (1=addition, 2=subtraction, 3=multiplication).
D	Kind of problem requested (1=easy, 2=medium, 3=hard).
H,L	Highest, lowest integers to allow as problem operands.
M	Answer column being worked on.
R\$	Operator's input character.
V	Value of R\$.
A	Ascii value of R\$.
X,Y	Horizontal, vertical screen position of cursor.

S	Starting address of CRT memory area.
R	Work variable.
J,K	Loop indices.
P	Poke character, also percentage correct.
CU,CL	Number of positions to move cursor up, left.

SUGGESTED PROJECTS

1. Keep track of problems missed and repeat them quickly for additional practice.
2. No negative operands or answers are currently allowed. Rewrite the problem generation routines and the operator's answer routines to allow the possibility of negative answers.
3. The answers are now restricted to three-digit numbers. However, the program will work fine for four-digit numbers if the operands of the problems were allowed to be large enough. Dig into the routines at lines 350 - 450 and 940 - 960. See how they work and then modify them to allow possible four-digit answers.
4. The operator cannot currently correct any mistakes he makes while typing in his answers. Modify the program to allow him to do so.
5. Modify the program to allow problems in division.

FLASHCARD

PURPOSE

There are certain things that the human mind is capable of learning only through repetition. Not many people can remember the multiplication tables after their first exposure, for example. The same applies to learning the vocabulary of a foreign language, the capital cities of the fifty states, or famous dates in history. The best way to learn them is to simply review them over and over until you have them memorized.

A common technique for doing this involves the use of flashcards. You write one half of the two related pieces of information on one side of a card, and the other half on the other side. After creating a set of these cards, you can drill yourself on them over and over until you always remember what's on the other side of each card.

But why waste precious natural resources by using cards? Use your computer instead. This program lets you create flashcards, drill using them, and save them on cassette tape for later review.

HOW TO USE IT

The program gives you six options. The first time you run it, you'll want to enter new flashcards, so you should reply with number 1.

To create the cards, the program asks you for each side of each flashcard, one at a time. First enter side one of the first card, and so on. As you enter the data, be careful not to use any

commas or colons unless the entire expression is enclosed in quotes. Also, be careful not to enter such a long stream of data that it goes to the next line on the screen. This can cause erroneous results.

At any time, you can enter the keyword `"*BACK"` to correct an erroneous entry. This causes the program to back up and ask you for the previous entry again.

As the program is currently written, you must enter at least five flashcards, and no more than twenty-five. We will show you how to change these limits in the "Easy Changes" section.

When you have entered all the flashcards you want, enter `"*END"` instead of side one of the next card. This puts the program back into "command" mode to ask you what to do next. If you want to quiz yourself on the cards you just entered, respond with the number 4.

The program flashes one side of one card on the screen for you. Both are chosen at random—the side and the card. Your job is to respond with the other side. If you enter it correctly, the program says "RIGHT!" If not, it tells you the correct response. In either event, the program continues by picking another side and card at random. This continues until you respond with `"*END"`, which tells the program you do not want to drill any more. It will then tell you how many you got right out of the number you attempted, as well as the percentage, and then return to command mode.

During the drill sequence, by the way, the program will not repeat a card that was used in the previous four questions (i.e., one less than the minimum number of cards you can enter).

To save a set of flashcards on cassette, use option number 3. The program will tell you to put the cassette into position and then enter a name for the file. You should give it a good descriptive name in order to remember what kind of flashcards they are in the future. Be sure to write the name on the cassette, too. After the flashcards have been copied to the cassette, the program will say "DONE" and return to the command mode.

The other commands are easily understood, so we will just explain them briefly. A little experimentation will show you how they work.

Command number 5 lets you verify that the set of flashcards just saved on tape are okay. You do not have to enter the name of the file—the same name is used that was used to save the file.

Command number 2 is used to load a flashcard tape that has been previously saved. The program asks for the name of the file, so it can scan the cassette until it finds the one you asked for. If you don't care or don't know the name of the file, you can load the first file that is found on the cassette by entering a null string for the name (two consecutive double quote marks).

Command number 6 ends the program.

EASY CHANGES

1. Change the limits of the number of flashcards that can be entered by altering line 130. L is the upper limit and M is the minimum. The current upper limit of twenty-five will fit in a PET with 4K of memory if each side of each flashcard averages no more than about twelve to fifteen characters in length. In an 8K PET, you can make L as large as about two hundred for flashcards this size. Do not make M much larger than about ten or so, or you will slow down the program and use more memory than you might want.
2. If you want to use some keywords other than “*END” and “*BACK”, substitute whatever you like in lines 210, 220, 240, and 440. Be sure you use expressions that are the same length as these two, however. If not, you will also need to change the last number just before each occurrence of the expression to correspond with the length.
3. To cause the program to always display side one of the flashcards (and ask you to respond with side two), insert this line:

380 GOTO 400

To cause it to always display side two, insert this:

380 GOTO 420

4. To eliminate the "echoing" on the screen of a tape file being verified, remove line 965. To do the same for a tape being loaded, remove line 1250.

MAIN ROUTINES

130 - 180	Initializes variables. Creates arrays. Displays title and options.
190 - 280	Accepts flashcards entered by operator.
290 - 610	Drills operator on flashcards in memory.
700 - 810	Saves flashcards on cassette file.
900 - 1030	Verifies that flashcards on cassette tape are the same as those in memory.
1150 - 1310	Loads flashcards from cassette file into memory.
1500 - 1540	Subroutine to display number right and attempted during drill.
1800 - 1810	Displays error message if operator tries to save flashcards on cassette before any are entered.
2000 - 2140	Displays options and analyzes response. Branches to appropriate routine.

MAIN VARIABLES

L	Upper limit of number of flashcards that can be entered.
M	Minimum number of flashcards that can be entered.
R	Subscript of random flashcard chosen during drill.
K	Number of flashcards entered.
W	Number of wrong responses.
C	Number of correct responses.
F\$	Array containing front side of flashcards (side 1).
B\$	Array containing back side of flashcards (side 2).
P	Array containing subscripts of M-1 previous flashcards during drill.
J	Loop and subscript variable.
C\$	The correct response during drill.

R\$	Response from operator. Also temporary string variable.
N\$	Name of cassette file.
E	Error flag--set to 1 if error occurs on cassette.
T\$	Temporary string variable.

SUGGESTED PROJECTS

1. Provide the capability to extend a set of flashcards. Create a new command that permits the operator to enter additional cards to be added to the end of the flashcards that are currently in memory.
2. Modify the program for use in a classroom environment. You might want to allow only command 2 to be used (to load a cassette tape), and then immediately go into "drill" mode for some fixed number of questions (maybe 20 or 50).

METRIC

PURPOSE

In case you don't realize it, we live in a metric world. The United States is one of the last holdouts, but that is changing rapidly. So if you're still inching along or watching those pounds, it's time to convert.

METRIC is an instructional program designed to familiarize you with the metric system. It operates in a quiz format; the program randomly forms questions from its data resources. You are then asked to compare two quantities—one in our old English units and one in the corresponding metric units. When you are wrong, the exact conversion and the rule governing it are given.

The two quantities to compare are usually within 50% of each other. Thus, you are constantly comparing an "English" quantity and a metric one which are in the same ball park. This has the effect of providing you some insight by sheer familiarity with the questions.

HOW TO USE IT

The first thing the program does is ask you how many questions you would like to do for the session. Any value of one or higher is acceptable.

The sample run shows how each question is formulated. A quantity in English units is compared with one in metric units. Either one may appear first in the question. Each quantity will have an integral value. The relating word ("longer," "hotter,"

“heavier,” etc.) indicates what type of quantities are being compared.

There are three possible replies to each question. Pressing **Y** or **N** means that you think the answer is yes or no, respectively. Pressing any other key indicates that you have no idea as to the correct answer.

If you answer the question correctly, you will be duly congratulated and the program will proceed to the next question. A wrong answer or a response of “no idea,” however, will generate some diagnostic information. The first value used in the question will be shown converted to its exact equivalent in the corresponding units. Also, the rule governing the situation will be displayed. At the end of any question, the program will request that you hit any key to proceed to the next question.

The program will continue generating the requested number of questions. Before ending, it will show you how many correct answers you gave and your percentage correct.

SAMPLE RUN

A METRIC QUIZ

HOW MANY QUESTIONS SHALL WE DO? 3

QUESTION 1 OF 3

IS 48 MILES LONGER THAN
92 KILOMETERS ? ("N" key pressed)

YOU SAY 'NO'

AND YOU'RE RIGHT - VERY GOOD!

*** HIT ANY KEY TO CONTINUE ***

QUESTION 2 OF 3

IS 73 DEGREES FAHRENHEIT HOTTER THAN
22 DEGREES CENTIGRADE ? ("Y" key pressed)

YOU SAY 'YES'

AND YOU'RE RIGHT - VERY GOOD!

*** HIT ANY KEY TO CONTINUE ***

QUESTION 3 OF 3

IS 79 KILOGRAMS HEAVIER THAN
152 POUNDS ? ("N" key pressed)

YOU SAY 'NO' BUT YOU'RE WRONG

```

-----
79 KILOGRAMS EQUALS
174.166097 POUNDS
---- THE RULE IS ----
1 KILOGRAM EQUALS
2.20463 POUNDS
*** HIT ANY KEY TO CONTINUE ***
YOU GOT 2 RIGHT OUT OF 3 QUESTIONS
PERCENTAGE CORRECT = 66.6666667

```

```

EASY CHANGES

1. To have the program always ask a fixed number of questions, change line 210 to set NQ to the desired value. For example:

210 NQ=10

will cause the program to do 10 questions.

2. There are currently seven conversions built into the program:

<i>N</i>	<i>Type</i>	<i>English Unit</i>	<i>Metric Unit</i>
1	temperature	degrees F.	degrees C.
2	speed	miles/hour	kilometers/hour
3	length	feet	meters
4	length	miles	kilometers
5	length	inches	centimeters
6	volume	gallons	litres
7	weight	pounds	kilograms

If you wish to be quizzed on only one type of question, set N to this value in line 600. Thus,

600 N=4

will cause the program to only produce questions comparing miles and kilometers. To add additional data to the program, see the first "Suggested Project."

3. You can easily have the questions posed in one "direction" only. To go only from English to metric units use

610 F=0

while to go from metric to English units use

610 F=1

4. You might want the converted value and governing rule to be displayed even when the correct answer is given. This is accomplished by changing line 740 and adding a line 745 as follows:

740 IF X=0 THEN PRINT:PRINT" AND YOU'RE RIGHT
-VERY GOOD!"

745 IF X=0 THEN NR=NR+1:GOSUB 800:GOTO 760

MAIN ROUTINES

- 150 - 160 Dimensions and initializes variables.
200 - 250 Mainline routine, drives other routines.

400 - 430	Reads and initializes data.
450	Displays header.
600 - 760	Forms and asks questions. Processes user's reply.
800 - 870	Displays exact conversion and governing rule.
900 - 920	Waits for user to hit any key.
1000 - 1999	Data statements.

MAIN VARIABLES

ND	Number of conversions in the data.
ESS\$,EP\$	String arrays of English units' names (singular, plural).
MS\$,MP\$	String arrays of metric units' names (singular, plural).
R\$	String array of the relation descriptors.
C	Array of the conversion factors.
Q	Work variable.
B\$	String constant of one blank character.
J	Current question number.
NR	Number of questions answered right.
P	Percentage answered right.
NQ	Number of questions in session.
N	Index number of current question in the data list.
F	Flag on question "direction" (0=English to metric; 1=metric to English).
V1,V2	Numeric values on left, right sides of the question.
V3	The correct value of the right hand side.
T	Flag on the question's correct answer (1=true; 0=false).
Q\$	User reply string.
R	User reply flag (0=no; 1=yes; 2=no idea).
X	User's result (0 if correct answer was given).

SUGGESTED PROJECTS

1. Each built-in conversion requires six elements of data in this order:

<i>Element</i>	<i>Data Description</i>
1	English unit (singular)
2	Metric unit (singular)
3	Relation descriptor (e.g., "hotter," "faster," etc.)

- 4 Conversion factor (from English to metric)
- 5 English unit (plural)
- 6 Metric unit (plural)

Each of these elements, except the fourth, is a string. The data statements in the listing should make clear how the information is to be provided. You can add new data to the program with appropriate data statements in this format. New data should be added after the current data, i.e. just before line 1999. Line 1999 is a special data statement to trigger the end of all data to the program. The program is dimensioned up to thirty entries while only seven are currently used. (Note: this format allows only conversions where one unit is a direct multiple of the other. Temperature, which does not fit this rule, is handled as a special case throughout the program.)

2. Convert the program to handle units conversion questions of any type.
3. Keep track of the questions asked and which ones were missed. Then do not ask the same questions too soon if they have been answered correctly. However, do re-ask those questions missed for additional practice.

NUMBERS

PURPOSE

This is an educational program for pre-school children. After a few weeks of watching Sesame Street on television, most three and four year old children will learn how to count from one to ten. The NUMBERS program allows these children to practice their numbers and have fun at the same time.

HOW TO USE IT

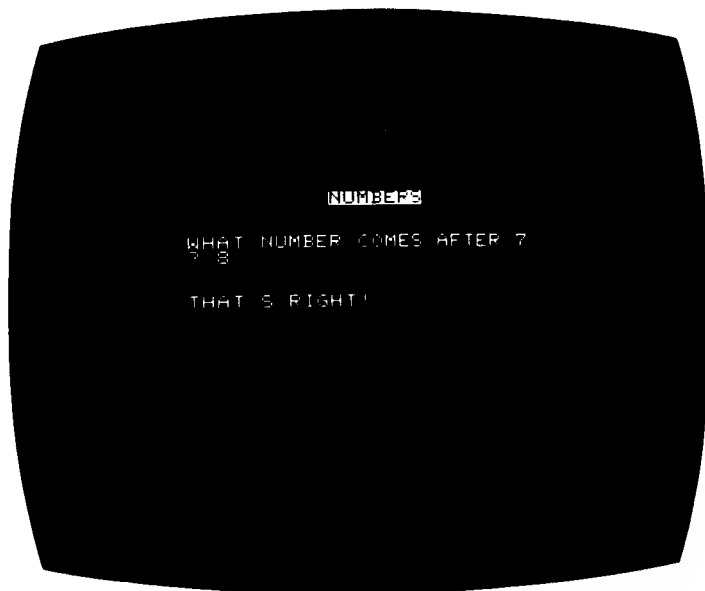

We know a child who learned how to type **LOAD** and **RUN** to get this program started before she turned three, but you'll probably have to help your child with this for a while. The program asks the question, "WHAT NUMBER COMES AFTER n?", where n is a number from one to nine. Even if the child can't read yet, he or she will soon learn to look for the number at the end of the line. The child should respond with the appropriate number, and then press the **RETURN** key.

If the answer is correct, the program displays the message "THAT'S RIGHT!", pauses for a couple of seconds, and then clears the screen and displays three geometrical shapes. In the upper left of the screen a square is drawn. In the lower center, a triangle is drawn. Then an asterisk (or a snowflake, perhaps?) is drawn in the upper right portion of the screen. After about a five second delay, the program clears the screen and asks another question. The same number is never asked twice in a row. The size of the three figures is chosen at random each time. Also, the graphics character used in drawing the asterisk is chosen at random (from a few possibilities) each time.

If the child provides the wrong answer, a message indicates the error and the same question is asked again.

The program keeps on going until you hit the **STOP** key. Remember that most children have a pretty short attention span, so please do not force your child to continue after his or her interest diminishes. Keep each session short and fun. This way, it will always be a treat to “play” with the computer.

SAMPLE RUN

The program asks what number comes after 7, and waits for a response. The operator says "8", and the program acknowledges that the answer is correct.

Because of the correct response, the program draws three geometric figures.

```

EASY CHANGES

1. Change the range of numbers that the program asks by altering the value of M in line 120. For a beginner, use a value of 3 for M instead of 9. Later, increase the value of M to 5, and then 8.
2. Alter the delay after "THAT'S RIGHT!" is displayed by altering the value of 1000 in statement 310. Double it to double the time delay, etc. The same can be done with the 3000 in line 800 to alter the delay after the figures are drawn.
3. To avoid randomness in the size of the figures that are drawn, replace line 330 with

330 E=10

Instead of 10, you can use any integer from 2 to 11.

4. To use a wider range of random graphics characters in drawing the asterisk, change the 7 in line 520 into a 19, and the 86 into 77.

5. To slowly increase the size of the figures from small to large as correct answers are given (and the reverse for incorrect answers), do the following:

- a. Replace the 10 in line 130 with a 2.
- b. Insert this line

225 E=E-3:IF E<2 THEN E=2

- c. Replace line 330 with the following:

330 E=E+2:IF E>11 THEN E=11

MAIN ROUTINES

120 - 160	Initializes variables. Clears screen.
170	Picks random integer from 1 to M.
180 - 240	Asks question. Gets answer. Determines if right or wrong.
310	Delays about 1½ seconds.
320 - 430	Draws a square.
450 - 500	Draws a triangle.
520 - 630	Draws an asterisk.
800	Delays about 5 seconds.
810 - 820	Clears screen. Goes back to ask next question.
900 - 910	Subroutine to POKE graphics character C to X,Y coordinate location on screen.

MAIN VARIABLES

M	Maximum number that will be asked.
S	Starting address of CRT screen.
E	Edge length of geometric figures.
R	Random integer in range from 1 to M.
P	Previous number that was asked.
R\$	Reply given by operator.
X,Y	Coordinates in CRT display.
C	Graphics character to be POKEd to CRT screen.
TS	Triangle's starting location (top).
A,B	X,Y coordinate values.
J	Subscript variable.

SUGGESTED PROJECTS

1. Modify the program to ask the next letter of the alphabet. Use the ASC and CHR\$ functions in picking a random letter from A to Y, and to check whether the response is correct or not.
2. Ask each number from 1 to M once (in a random sequence). At the end of the sequence, repeat those that were missed.
3. Add different shapes to the graphics display that is done after a correct answer. Try an octagon, a diamond, and a rectangle. Or, combine this program with one of the graphics display programs.

TACHIST

PURPOSE

This program turns your computer into a tachistoscope (tah-KISS-tah-scope). A tachistoscope is used in reading classes to improve reading habits and, as a result, improve reading speed. The program displays a word or phrase on the screen for a fraction of a second, then asks you what it was. With a little practice, you will find that you can read phrases that are displayed for shorter and shorter time periods.

HOW TO USE IT

The program starts off by displaying a brief introduction and waiting for you to press any key (except the **STOP** key or shift keys, of course). After you press a key, the screen is blanked out except for two horizontal dash lines in the upper left-hand corner. After two and a half seconds, a phrase is flashed on the screen between the two lines. Then the screen is blanked again, and you are asked what the phrase was.

If you respond correctly, the next phrase is displayed for a shorter time period (.05 seconds less). If you respond incorrectly, the program shows you the correct phrase, and the next phrase is displayed for a longer period of time (.05 seconds more).

The fastest the computer can display a phrase and erase it is about .02 seconds (one-fiftieth). See if you can reach the top speed and still continue to read the phrases correctly.

A great deal of research has been done to determine how people read and what they should do to read both faster and with better comprehension. We will not try to explain it all (see the bibliography), but a couple of things are worth mentioning.

To read fast, you should not read one word at a time. Instead, you should learn to quickly read an entire phrase at once. By looking at a point in the center of the phrase (and slightly above it), your eyes can see the whole phrase *without* the necessity of scanning it from left to right, word by word. Because the tachistoscope flashes an entire phrase on the screen at once, it forces you to look at a single point and absorb the whole phrase, rather than scanning left to right, word by word.

If you can incorporate this technique into your reading and increase the width of the phrases you absorb, your reading speed can increase dramatically.

SAMPLE RUN

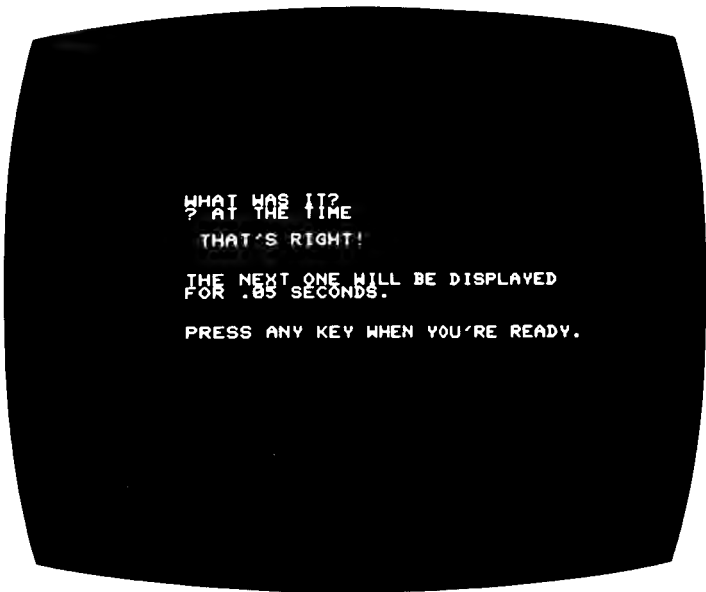

The program displays an introduction, then waits.

The program clears the screen and displays two parallel lines in the upper left corner of the screen for a couple of seconds.

The program flashes a short phrase (chosen at random) between the two lines for one tenth of a second, then clears the screen.

WHAT WAS IT?
? AT THE TIME
THAT'S RIGHT!
THE NEXT ONE WILL BE DISPLAYED
FOR .05 SECONDS.
PRESS ANY KEY WHEN YOU'RE READY.

The program asks what the phrase was. The operator responds correctly. The program acknowledges the correct response, and indicates that the next phrase will be shown for a shorter length of time.

9999 DATA XXX
```

EASY CHANGES

1. Change the phrases that are displayed by changing the DATA statements that start at line 910. Add more and/or replace those shown with your own phrases or words. Line 140 must specify a number that is at least as large as the number of DATA statements. So, to allow for up to 100 DATA statements, change line 140 to say

140 L=100

Be sure to enter your DATA statements in the same form shown in the program listing. To begin with, you may want to start off with shorter phrases or single words. Later, try longer phrases. Do not alter line 9999, which has to be the last DATA statement. In a 4K PET, you have room for about 60 phrases of the approximate size shown in the program listing. In an 8K PET, you can probably have over 200 of them. Be sure to have at least 6.

2. To change the length of time the first phrase is displayed, change the value of T in line 120. If one-tenth of a second is too fast, try two-tenths. Use a multiple of .05 seconds, or else make it .02 seconds (the maximum speed).
3. To cause all phrases to be displayed for the same length of time, remove lines 570 and 720.

4. If you want to change the waiting period before the phrase is flashed on the screen, change the 1500 in line 465. To make the delay five seconds, change it to 3000. To make it one second, change it to 600.
5. To put the program into a sort of flashcard mode, in which the phrases are flashed, but no replies are necessary, insert these two lines:

515 GOTO 710

715 GOTO 590

This will cause each phrase to be flashed (all for the same length of time), and then displayed again so you can verify what it was.

MAIN ROUTINES

120 - 150	Initializes variables
160 - 220	Reads DATA statements into T\$ array.
260 - 380	Displays introduction.
400 - 420	Waits for operator to press a key.
430 - 450	Picks random phrase from T\$ array. Ensures no duplication from previous five phrases.
460 - 465	Clears screen and displays horizontal lines.
470 - 500	Displays phrase for appropriate length of time.
505 - 530	Waits, then asks what the phrase was.
550	Determines if typed phrase matches the phrase displayed.
560 - 640	Shortens time for next phrase if reply was correct. Saves subscript to avoid repetition. Goes back to 400.
700 - 740	Shows what phrase was. Lengthens time for next phrase. Ensures that time period is a multiple of .05 seconds.
800 - 810	Special routine to display phrase for shortest time (about .02 seconds).
840 - 870	Subroutine to display horizontal dash lines.
910 - 9999	DATA statements with phrases to be displayed.

MAIN VARIABLES

T	Time (seconds) that phrase will be displayed.
J	Number of "jiffies" that the phrase will be displayed.

B	ASCII number for character to clear screen.
L	Limit of number of phrases.
T\$	Array of phrases (read into from DATA statements).
C	Count of number of phrases actually read.
R\$	Temporary string variable. Also, reply of operator.
R	Work variable. Also, subscript of phrase to be displayed.
P1,P2, P3,P4,P5	Subscripts of the five previous phrases.
S	Starting time of display of phrase (in jiffies).
K	Temporary work variable.

SUGGESTED PROJECTS

1. Instead of picking phrases at random, go through the list once sequentially. Change line 250 to set R to zero, and line 430 to add one to R, then check if R is greater than C.
2. Instead of only verifying that the current phrase does not duplicate any of the previous five phrases, modify the program to avoid duplication of the previous ten or more. Changes will be needed to lines 440, 450, and 600.
3. Keep score of the number of correct and incorrect replies, and display the percentage each time. Alternatively, come up with a rating based on the percentage correct and the speed attained, possibly in conjunction with a difficulty factor for the phrases used.
4. Add the capability to the program to also have a mode in which it can display a two to seven digit number, chosen at random. Have the operator try several of the numbers first (maybe five-digit ones) before trying the phrases. The phrases will seem easy after doing the numbers.

VOCAB

PURPOSE

Did you ever find yourself at a loss for words? Well, this vocabulary quiz can be used in a self-teaching environment or as reinforcement for classroom instruction to improve your ability to remember the jargon of any subject. It allows you to drill at your own pace, without the worry of ridicule from other students or judgment by an instructor. When you make mistakes, only the computer knows, and it's not telling anyone except you. Modifying the program to substitute a different vocabulary list is very simple, so you can accumulate many different versions of this program, each with a different set of words.

HOW TO USE IT

This program is pretty much self-explanatory from the sample run. After you enter "RUN," it asks you how many questions you would like. If you respond with a number less than five, you will still do five. Otherwise, you will do the number you enter.

Next, you get a series of multiple choice questions. Each question is formatted in one of two ways—either you are given a word and asked to select from a list of definitions, or you are given a definition and asked to select from a list of words. The format is chosen at random. You respond with the number of the choice you think is correct. If you are right, you are told so. If not, you are shown the correct answer. From the second question on, you are shown a status report of the number correct out of the number attempted so far.

Finally, after the last question, you are shown the percentage you got correct, along with a comment on your performance. Then you have the option of going back for another round of questions or stopping.

SAMPLE RUN

RUN

**** VOCABULARY QUIZ ****

THIS PROGRAM WILL TEST YOUR KNOWLEDGE
OF SOME USEFUL VOCABULARY WORDS

HOW MANY QUESTIONS SHALL WE DO? 5

1 -- WHAT WORD MEANS ALL-KNOWING?

- 1 -- LACONIC
- 2 -- HEDONISTIC
- 3 -- OMINOUS
- 4 -- CONGENITAL
- 5 -- OMNISCIENT

? 5

RIGHT!

2 -- WHAT DOES PARSIMONIOUS MEAN?

- 1 -- INDIFFERENT OR UNINTERESTED
- 2 -- KEEN IN JUDGMENT
- 3 -- STINGY OR FRUGAL
- 4 -- WEAK OR EXHAUSTED
- 5 -- OF UNKNOWN OR HIDDEN ORIGIN

? 4

NO, THE ANSWER IS NUMBER 3

YOU HAVE 1 RIGHT OUT OF 2 QUESTIONS.

(... later)

YOU HAVE 3 RIGHT OUT OF 5 QUESTIONS.

THAT'S 60 PERCENT.
NOT BAD, BUT ROOM FOR IMPROVEMENT.

WANT TO TRY AGAIN? NO

CHECK YOU LATER.

7999 DATA XXX
```

EASY CHANGES

1. Add more DATA statements between lines 7000 and 7999, or replace them all with your own. Be careful not to use two or more words with very similar definitions; the program might select more than one of them as possible answers to the same question. Note that each DATA statement first has the vocabulary word, then a comma, and then the definition or synonym. Be sure there are no commas or colons in the definition (unless you enclose the definition in quotes). If you add more DATA statements, you have to increase the value of D in line 2020 to be at least one greater than the number of words. The number of DATA statements you can have depends on how long each one is and how much user memory your computer has. Using DATA statements that average the same length as these, you can probably have about thirty of them in a 4K PET, or as many as 130 in an 8K model. Be sure to leave statement 7999 as it is—it signals that there are no more DATA statements.
2. To get something other than five choices for each question, change the value of C in line 2010. You might want only three or four choices per question.
3. If you do not want to be given a choice of how many questions are going to be asked, remove lines 1110 through 1140 and insert the following lines:

```
1110 PRINT"WE'LL DO TEN QUESTIONS."  
1120 L=10
```

This will always cause ten questions to be asked. Of course, you can use some number other than ten if you want.

MAIN ROUTINES

- | | |
|-------------|--|
| 300 - 910 | Mainline routine. Calls major subroutines. |
| 1000 - 1200 | Prints introduction. Initializes RND function. Determines number of questions to be asked. |

2000 - 2300	Reads vocabulary words and definitions into arrays. Performs housekeeping.
3000 - 3200	Selects choices for answers and determines which will be the correct one.
4000 - 4210	Determines in which format the question will be asked. Asks it.
5000 - 5330	Accepts answer from operator. Determines if right or wrong. Keeps score. Saves subscripts of last three correct answers.
6000 - 6250	Gives final score. Asks about doing it again.
7000 - 7999	DATA statements with vocabulary words and definitions.

MAIN VARIABLES

E	Set to 1 to avoid repeating introduction after the first round.
L	Limit of number of questions to ask.
R	Work variable to initialize RND. Also used for operator's reply to each question.
C	Number of choices of answers given for each question.
D	At least one greater than number of DATA statements. Used to DIM arrays.
D\$	Array of vocabulary words.
E\$	Array of definitions.
P	Array for numbers of possible answers to each question.
J	Work variable (subscript for FOR-NEXT loops).
Q	Number of questions asked so far (later used to calculate percent correct).
Q1	Number of questions correct so far.
P	Work variable.
P1,P2,P3	Last three correct answers.
A	Subscript of correct answer in P array.
M	Work variable to decide which way to ask question.
RS	Yes or no reply about doing another round.

SUGGESTED PROJECTS

1. Modify lines 6030 through 6200 to display the final evaluation messages based on a finer breakdown of the percent correct. For example, show one message if 100 percent, another if 95 to 99, another if 90 to 94, etc.
2. Ask the operator's name in the introduction routine, and personalize some of the messages with his/her name.
3. Instead of just checking about the last three questions, be sure that the next question has not been asked in the last eight or ten questions. (Check lines 3045 and 5300 through 5320.)
4. Keep track of which questions the operator misses. Then, after going through the number of questions he/she requested, repeat those that were missed.

Section 3

Game Programs

INTRODUCTION TO GAME PROGRAMS

Almost everyone likes to play games. Computer games are a fun and entertaining use of your PET. Besides providing relaxation and recreation, they have some built-in practical bonuses. They often force you to think strategically, plan ahead, or at least be orderly in your thought processes. They are also a good way to help some friends over their possible “computer phobia.” We present a collection of games to fit any game playing mood.

Maybe you desire a challenging all-skill game? Like chess or checkers, WARI involves no luck and considerable thinking. The PET will be your opponent, and a formidable one indeed.

Perhaps you’re in the mood for a game with quick action and mounting excitement. GROAN is a fast-paced dice game involving mostly luck with a dash of skill (or intuition) thrown in. The PET is ready for your challenge anytime.

JOT is a word game. You and the PET each take secret words and then try to home in on each other’s selection.

Do you like solving puzzles? If so, try DECODE. The PET will choose a secret code and then challenge you to find it. How fast can you do it?

Graphic electronic arcade games are a prevalent landmark of the late seventies. We include two such games. ROADRACE puts you behind the wheel of a high speed race car. You must steer accurately to stay on course. OBSTACLE lets you and a friend compete in a game of cut and thrust. Each of you must avoid crossing the path laid by the other, and by yourself!

DECODE =

Master Mind.

PURPOSE

Decode is really more of a puzzle than a game, although you can still compete with your friends to see who can solve the puzzles the fastest. Each time you play, you are presented with a new puzzle to solve.

The object is to figure out the computer's secret code in as few guesses as possible. The program gives you information about the accuracy of each of your guesses. By carefully selecting your guesses to make use of the information you have, you can determine what the secret code must be in a surprisingly small number of guesses. Five or six is usually enough.

The first few times you try, you will probably require quite a few more guesses than that, but with practice, you'll discover that you can learn a lot more from each guess than you originally thought.

HOW TO USE IT

The program starts off by displaying a brief introduction. Here are some more details.

The program selects a secret code for you to figure out. The code is a four digit number that uses only the digits 1 through 6. For example, your PET might pick 6153 or 2242 as a secret code.

Your object is to guess the code in the fewest possible guesses. After each of your guesses, the program tells you a "black" and a "white" number. The black number indicates the number of

digits in your guess that were correct—the digit was correct *and* in the correct position. So, if the secret code is 6153 and your guess is 4143, you will be told that black is 2 (because the 1 and the 3 will have been correct). Of course, you aren't told *which* digits are correct. That is for you to figure out by making use of the information you get from other guesses.

Each of the white numbers indicates a digit in your guess that was correct, but which is in the wrong position. For example, if the secret code is 6153 and your guess is 1434, you will be told that white is 2. The 1 and 3 are correct, but in wrong positions.

The white number is determined by ignoring any digits that accounted for a black number. Also, a single position in the secret code or guess can only account for one black or white number. These facts become significant when the secret code and/or your guess have duplicate digits. For example, if the code is 1234 and your guess is 4444, there is only one black, and no whites. If the code is 2244 and your guess is 4122, there are no blacks and three whites.

This may sound a little tricky, but you will quickly get the hang of it.

At any time during the game, you can ask for a "SUMMARY" by entering an S instead of a guess. This causes the program to clear the screen and display each guess (with the corresponding result) that has occurred so far.

Also, if you get tired of trying and want to give up, you can enter a Q (for "quit") to end your misery and find out the answer. Otherwise, you continue guessing until you get the code right (four black, zero white), or until you have used up the maximum of twelve guesses.

SAMPLE RUN

```

**** DECODE ****

FIGURE OUT A 4 POSITION CODE
USING THE DIGITS 1 THRU 6

'BLACK' INDICATES A CORRECT DIGIT
IN THE RIGHT POSITION.
'WHITE' INDICATES SOME OTHER CORRECT
DIGIT, BUT IN THE WRONG POSITION.

I'VE CHOSEN MY SECRET CODE.
GUESS NUMBER 1 ? 6413
GUESS NO. 1 -- BLACK = 2  WHITE = 0
GUESS NUMBER 2 ? ■

```

The program displays an introduction, chooses its secret code, and asks for the operator's first guess. After the operator makes a guess, the program responds with a "black" and a "white" number, and asks for the second guess.

```

                SUMMARY
NO.    GUESS    BLACK    WHITE
  1     6413      2       0
  2     6452      1       0
  3     6611      0       0
  4     4433      3       0

GUESS NUMBER 5 ? 4443
GUESS NO. 5 -- BLACK = 4  WHITE = 0

YOU GOT IT IN 5 GUESSES.
...THAT'S PRETTY GOOD
WANT TO TRY AGAIN?

```

Later in the same game, the operator asks for a summary, then makes the guess that turns out to be correct. The program acknowledges that the guess is correct and asks about trying another game.

2240 GOTO 2080

```

EASY CHANGES

1. Modify line 120 to change the complexity of the code and/or the number of guesses you are allowed. For example, the following line would allow fifteen guesses at a five position code using the digits 1 through 8:

```
120 D=8:P=5:L=15
```

The introduction will automatically reflect the new values for D and P. Be sure that neither D nor P is set greater than 9.

2. To change the program so it will always display the "Summary" information after each guess automatically, replace line 280 with this:

```
280 GOTO 500
```

MAIN ROUTINES

120 - 170	Initializes variables. Displays introduction. Chooses secret code.
180 - 240	Gets a guess from operator. Analyzes reply. Displays result.
250	Determines if operator guessed correctly.
260 - 280	Saves guess. Adds one to guess counter. Determines if limit on number of guesses was exceeded.
300 - 310	Subroutine to initialize variables.
370 - 430	Subroutine to choose secret code and inform operator.
500 - 570	Subroutine to display summary of guesses so far.
600 - 680	Subroutine to slowly display secret code when operator quits.
700 - 790	Subroutine to determine if operator's guess was legal.

800 - 930	Subroutine to determine number of black and white responses for the guess.
1000 - 1020	Subroutine to display number of black and white responses for the guess.
1200 - 1340	Subroutine to display title and introduction.
2000 - 2130	Subroutine to analyze operator's performance after correct answer is guessed and ask about playing again.
2200 - 2240	Subroutine to display secret code after operator exceeds limit of number of guesses.

MAIN VARIABLES

D	Number of possible digits in each position of the code (i.e., a digit from 1 to D).
P	Number of positions in the code.
L	Limit of number of guesses that can be made.
G\$	Array in which guesses are saved.
G,C	Work arrays in which each guess is analyzed.
B,W	Arrays in which the number of black and white responses is saved for each guess.
R,H	Work variables.
G	Counter of the number of guesses made.
A\$	Reply by the operator.
C\$	Secret code chosen by the program.
J,K	Loop variables.
B,W	Number of black and white responses for this guess.
B\$	String with message about operator's performance.

SUGGESTED PROJECTS

1. Change the analysis at the end of the game to take into account the difficulty of the code as well as the number of guesses it took to figure the code out. A four position code using the digits 1 through 6 has 1296 possibilities, but a five position code using 1 through 8 has 32768 possibilities. Change lines 2020 through 2060 to determine the message to be displayed based on the number of possibilities in the code as well as G.
2. At the beginning of the game, give the operator the option of deciding the complexity of the code. Ask for the number of

positions and the number of digits. Make sure only “reasonable” numbers are used—do not try to create a code with zero positions, for example. Another approach is to ask the operator if he/she wants to play the easy, intermediate, or advanced version. Then set the values of D and P accordingly. Suggestions are:

Easy:	D=3 and P=3
Intermediate:	D=6 and P=4
Advanced:	D=8 and P=5

3. In addition to using the number of guesses to determine how well the operator did, keep track of the amount of time.

GROAN

PURPOSE

Do you like the thrills of fast-paced dice games? If so, GROAN is right up your alley. It is a two-person game with the computer playing directly against you. There is a considerable amount of luck involved. However, the skill of deciding when to pass the dice to your opponent also figures prominently.

The PET will roll the dice for both players, but don't worry—it will not cheat! (We wouldn't think of stooping to such depths.)

Why is the game called GROAN? You will know soon after playing it.

HOW TO USE IT

The game uses two dice. They are just like regular six-sided dice except for one thing. The die face where the "1" would normally be has a picture of a frowning face instead. The other five faces of each die have the usual numbers two through six on them.

The object is to be the first player to achieve a score agreed upon before the start of the game. Players alternate taking turns. A turn consists of a series of dice rolls (at least one roll, possibly several) subject to the following rules.

As long as no frown appears on either die, the roller builds a running score for this current series of rolls. After each roll with no frown, he has the choice of rolling again or passing the dice to his opponent. If he passes the dice, his score achieved on the current series is added to any previous total he may have had.

But if he rolls and a frown appears, he will be groaning. A frown on only one die cancels any score achieved for the current series of rolls. Any previous score is retained in this case. However, if he rolls a double frown, his entire previous total is wiped out as well as his current total. Thus, he reverts back to a total score of zero—true despair.

The program begins by asking what the winning score should be. Values between 50 and 100 tend to produce the best games, but any positive value is acceptable. Next, a simulated coin toss randomly decides who will get the first roll.

Each dice roll is portrayed with a short graphics display. The dice are shown rotating and then the outcome is displayed pictorially. Before each roll, the PET indicates whose roll is coming up.

Each roll is followed by a display of the scoreboard. This scoreboard gives all relevant information: score needed to win, both players' scores before the current series of rolls, and the total score for the current series.

If a frown should appear on a die, the scoreboard will indicate the current running total as zero. In addition, the previous total will become zero in the case of the dreaded double frown. In either case, the dice will be passed automatically to the next player.

If a scoring roll results, the roller must decide whether to roll again or to pass the dice. The program has a built-in strategy to decide this for the PET. For you, the question will be asked after the scoreboard is displayed. The two legal replies are **P** and **R**. The **R** means that you wish to roll again. The **P** means that you choose to pass the dice to the PET. If you should score enough to win, you must still pass the dice to add the current series to your previous total.

The first player to pass the dice with a score greater than or equal to the winning score is the victor. This will surely cause his opponent to GROAN. The PET will acknowledge the winner before signing off.

SAMPLE RUN

The operator has decided to challenge the PET to a fifty point game of GROAN. The computer wins the coin toss and gets the first dice roll.

The PET's roll, however, results in a "groan" and a four. This scores no points and the dice pass to the operator.

Much later in the same game, the operator rolls a 7 to start a series of rolls. The score was operator-29, PET-20 before the roll. The operator must now decide whether to pass the dice or risk rolling again.

1110 X=1:RETURN
```

EASY CHANGES

1. If you wish to set the program for a fixed value of the winning score, it can be done by changing line 210. Simply set W to the winning score desired. For example:

```
210 W=100
```

would make the winning score 100.

2. The rotating dice graphics display before each roll can be eliminated by

```
505 GOTO 550
```

This has the effect of speeding up the game by showing each dice roll immediately.

3. After you play the game a few times, you may wish to change the delay constants in lines 830 and 840. They control the “pacing” of the game; i.e., the time delays between various messages, etc. To speed up the game try

```
830 FOR K=1 TO 750:NEXT:RETURN
```

```
840 FOR K=1 TO 2500:NEXT:RETURN
```

Of course, if desired, the constants can be set to larger values to slow down the pacing.

MAIN ROUTINES

150 - 180	Initializes constants.
200 - 280	Initial display. Gets winning score.
300 - 390	Human rolls.
400 - 470	PET rolls.
500 - 590	Determines dice roll. Drives its display.
600 - 620	Determines moving dice locations. Draws and erases dice.
650 - 690	Draws die outline.
700 - 770	Draws die face.
800 - 820	Displays groan messages.
830 - 840	Delay loops.
850 - 960	Displays scoreboard.

- 970 - 990 Ending messages.
 1000 - 1110 PET's strategy. Sets X=0 to stop rolling or X=1 to continue rolling.

MAIN VARIABLES

W	Amount needed to win.
H	Previous score of human.
P	Previous score of PET.
T	Score of current series of rolls.
X	PET strategy flag (0=stop rolling; 1=roll again).
L	Cutoff threshold used in PET's built-in strategy.
V	Score PET would have if it passed the dice.
DL	Delay length.
B,D,U	CHR\$ arguments for border, divider, underline.
S	Starting address of CRT memory area.
Q,Q\$	Work variable, work string variable.
J,K	Loop indices.
P\$	String of name of current roller.
R1,R2	Outcome of roll for die 1, die 2.
R	Outcome of a die roll.
F	Result of roll (0=no frown; 1=one frown; 2=double frown).
C1,C2	Poke address of die 1, die 2.
C	Poke address of a die.
NT	Argument for TAB function.

SUGGESTED PROJECTS

1. The PET's built-in strategy is contained from line 1000 on. Remember, after a no frown roll, the PET must decide whether or not to continue rolling. See if you can improve on the current strategy. You may use, but not modify, the variables P, T, H, W. The variable X must be set before returning. Set X=0 to mean the PET passes the dice or X=1 to mean the PET will roll again.
2. Ask the operator for his/her name. Then personalize the messages and scoreboard more.
3. Dig into the workings of the graphics routines connected with the dice rolling. Then modify them to produce new, perhaps more realistic, effects.

JOT

PURPOSE

JOT is a two player word game involving considerable mental deduction. The PET will play against you. But be careful! You will find your computer quite a formidable opponent.

The rules of JOT are fairly simple. The game is played entirely with three-letter words. All letters of each word must be distinct—no repeats. (See the section on Easy Changes for further criteria used in defining legal words.)

To begin the game, each player chooses a secret word. The remainder of the game involves trying to be the first player to deduce the other's secret word.

The players take turns making guesses at their opponent's word. After each guess, the asker is told how many letters (or hits) his guess had in common with his opponent's secret word. The position of the letters in the word does not matter. For example, if the secret word was "own," a guess of "who" would have 2 hits. The winner is the first person to correctly guess his opponent's secret word.

HOW TO USE IT

The program begins with some introductory messages while asking you to think of your secret word. It then asks whether or not you wish to make the first guess. This is followed by you and the PET alternating guesses at each other's secret word.

After the PET guesses, it will immediately ask you how it did. Possible replies are 0, 1, 2, 3, or R. The response of R (for right)

means the PET has just guessed your word correctly—a truly humbling experience. The numerical replies indicate that the word guessed by the PET had that number of hits in your secret word. A response of 3 means that all the letters were correct, but they need to be rearranged to form the actual secret word (e.g. a guess of “EAT” with the secret word being “TEA”).

After learning how it did, the computer will take some time to process its new information. If this time is not trivial, the PET will display the message: “I’M THINKING” so you do not suspect it of idle daydreaming. If it finds an inconsistency in its information, it will ask you for your secret word and then analyze what went wrong.

When it is your turn to guess, there are two special replies you can make. These are the single letters S or Q. The S, for summary, will display a table of all previous guesses and corresponding hits. This is useful as a concise look at all available information. It will then prompt you again for your next guess. The Q, for quit, will simply terminate the game.

When not making one of these special replies, you will input a guess at the PET’s secret word. This will be, of course, a three letter word. If the word used is not legal, the computer will so inform you. After a legal guess, you will be told how many hits your guess had. If you correctly guess the PET’s word, you will be duly congratulated. The computer will then ask you for your secret word and verify that all is on the “up and up.”

SAMPLE RUN

JOT

JUST A MOMENT PLEASE

THANKS, NOW LET’S EACH THINK
OF OUR SECRET WORD

(THIS TAKES ME A WHILE . . .)

I’VE ALMOST GOT IT . . .

OK, DO YOU WANT TO GO FIRST? NO

MY GUESS IS -- NIP
HOW DID I DO (Ø-3 OR R)? 1

I'M THINKING ...

YOUR GUESS (OR S OR Q)? DOG
OF HITS IS 1

MY GUESS IS -- NOR
HOW DID I DO (Ø-3 OR R)? Ø

I'M THINKING ...

⋮

(later in the same game)

⋮

YOUR GUESS (OR S OR Q)? S

YOUR GUESSES		SUMMARY	MY GUESSES	
WORD	HITS		WORD	HITS
DOG	1	1	NIP	1
CAT	Ø	2	NOR	Ø
LIP	Ø	3	DIG	Ø
SON	Ø	4	PUT	2
		5	PUB	1

YOUR GUESS (OR S OR Q)? FED
OF HITS IS 2

MY GUESS IS -- PET
HOW DID I DO (Ø-3 OR R)? R

IT SURE FEELS GOOD

MY WORD WAS - WED

HOW ABOUT ANOTHER GAME? NO
READY.

```

EASY CHANGES

1. It is fairly common for players to request a summary before most guesses that they make. If you want the program to automatically provide a summary before each guess, change line 500 to read

```
500 GOSUB 1000:PRINT:INPUT"YOUR GUESS (OR Q)";P$
```

2. The maximum number of guesses allowed, M, can be changed in line 150. You may wish to increase it in conjunction with Suggested Project 2. You might decrease it to free some memory needed for other program additions. The current value of twenty-five is really somewhat larger than necessary. An actual game almost never goes beyond fifteen guesses. To set M to 15 change line 150 to read

```
150 M=15:N=406:V=250
```

3. Modifying the data list of legal words is fairly easy. Our criteria for legal words was as follows: they must have three distinct letters and *not* be

- capitalized
- abbreviations
- interjections (like “ugh”, “hey” etc.)
- specialized words (like “ohm”, “sac”, “yaw” etc.)

In line 150, N is set to be the total number of words in the data list. The data list itself is from line 5000 on.

To add word(s), do the following. Enter them in data statements after the current data (use line numbers larger than 5570). Then redefine the value of N to be 406 plus the number of new words added. For example, to add the words "ohm" and "yaw" onto the list, change line 150 to read

```
150 M=25:N=408:V=250
```

and add a new line

```
5580 DATA OHM,YAW
```

The list is limited to about 460 words before an 8K PET will run out of memory.

To delete word(s), the opposite must be done. Remove the words from the appropriate data statement(s) and decrease the value of N accordingly. If you should ever reduce N below the value of V, redefine V to this new value of N. V, like N, is defined in line 150. (The array shuffling routine at line 2200 assumes N will have a value of at least 100.)

MAIN ROUTINES

150 - 170	Dimensions arrays.
200 - 330	Initializes new game.
500 - 570	Human guesses at the PET's word.
600 - 680	PET guesses.
800 - 870	Evaluates human's possible secret words. Moves them to the front of A\$-B\$ array.
900 - 950	Processes inconsistency in given information.
1000 - 1090	Displays the current summary table.
1100 - 1130	Inquires about another game.
1500 - 1610	Compares a guess with key word.
1800 - 1830	Checks if input word is legal.
2000 - 2010	Sets Q\$ to Q'th element of A\$-B\$ array.
2100 - 2110	Sets P'th element of A\$-B\$ array to P\$.
2200 - 2240	Shuffles A\$-B\$ array randomly.
2400 - 2420	Swaps elements A and B in the A\$-B\$ array.
2600 - 2610	Breaks word Q\$ into separate letters.
3000 - 3010	Fills A\$-B\$ array from data.
3200 - 3220	Post-mortem after PET wins.
3400 - 3460	Post-mortem after human wins.

3600 - 3610 Error routine - too many guesses.
 5000 - 5520 Data.

MAIN VARIABLES

N	Total number of data words.
V	Size of A\$ array (250).
M	Maximum number of guesses allowed.
A\$	String array holding first V data words.
B\$	String array holding last (N-V) words.
G1\$,G2\$	String arrays of human's, PET's guesses.
H1,H2	Arrays of human's, PET's hits corresponding to G1\$, G2\$.
G1,G2	Current number of human's, PET's guesses.
M\$	PET's secret word.
M1\$,M2\$,M3\$	First, second, and third letters of a word.
P\$,Q\$	String temporaries and work variables.
L	Current number of human's possible secret words.
F	Flag for input word legality.
H	Number of hits in last guess.
K	Formatting variable used in the summary display.
A,B	A\$ B\$ array locations to be swapped.
J,P,Q	Temporaries; array and loop indices.

SUGGESTED PROJECTS

1. Additional messages during the course of the game can personify the program even more. After the PET finds out how its last guess did, you might try an occasional message like one of these:

JUST AS I THOUGHT . . .

HMM, I DIDN'T EXPECT THAT . . .

JUST WHAT I WAS HOPING TO HEAR . . .

The value of L is the number of words to which the computer has narrowed down the human's secret word. You might check its value regularly and when it gets low, come out with something like

BE CAREFUL, I'M CLOSING IN ON YOU.

2. Incorporate a feature to allow the loser to continue guessing at the other's word. The summary display routine will already work fine even if G1 and G2 are very different from each other. It will display a value of "9" for the number of hits corresponding to the correct guess of a secret word.
3. Try to speed up some of the program execution. It is slow during the initial array shuffling and after finding out how its first few guesses did. There are several reasons for this. One is that PET Basic allows a maximum array size of 255. This forces keeping the words in two "continuous" arrays, namely A\$ and B\$. Much time is "wasted" in checking which array an element is in. Try digging into the internal workings of the program with an eye toward lowering the execution time. Happy hunting!

OBSTACLE

PURPOSE

This program allows you and a friend (or enemy) to play the game of OBSTACLE, an arcade-like game that's one of our favorites. A combination of physical skills (reflex speed, hand to eye coordination, etc.) and strategic skills are needed to beat your opponent. Each game generally takes only a minute or two, so you'll want to play a match of several games to determine the better player.

HOW TO USE IT

The object of the game is to keep moving longer than your opponent without bumping into an obstacle. When the program starts, it asks in turn for the name of the player on the left and on the right. Then it displays the playing field, shows the starting point for each player, and tells you to press any key to start.

After a key is pressed, each player begins moving independently in one of four random directions—up, down, left, or right. As each player moves, he or she builds a “wall” inside the playing field. The computer determines the speed of the move; the player can only control his own direction. The player on the left can change direction to up, down, left, or right by pressing the key **W**, **X**, **A**, or **D**, respectively. The player on the right does the same by using the keys for **8**, **2**, **4**, and **6**. Find these keys on your PET's keyboard and you will see the logic behind these choices.

The first time either player bumps into the wall surrounding the playing field or the obstacle wall built by either player, he loses. When this happens, the program indicates the point of impact for a few seconds and displays the name of the winner. Then the game starts over.

The strategic considerations for this game are interesting. Should you attack your opponent, trying to build a wall around him that he must crash into? Or should you stay away from him and try to make efficient moves in an open area until your opponent runs out of room on his own? Try both approaches and see which yields the most success.

When pressing a key to change direction, be sure to press it quickly and release it. *Do not* hold a key down—you might inhibit the computer from recognizing a move your opponent is trying to make. Once in a while, only one key will be recognized when two are hit at once.

SAMPLE RUN

The program starts off by asking for the names of the two players.

The program draws the playing field and waits for a key to be pressed.

The program redraws the playing field and starts both players moving in a random direction (in this case, both start moving to the left). Phil (on the right) doesn't change directions soon enough and crashes into the wall, making Tom the winner.

```

EASY CHANGES

1. To speed the game up, change the 10 in line 255 to a 5 or so. To slow it down, make it 15 or 20.
2. To make both players always start moving upward at the beginning of each game (instead of in a random direction), insert the following statement:

```
168 AD=1:BD=1
```

To make the players always start off moving toward each other, use this statement instead:

```
168 AD=4:BD=3
```

3. You can change the graphics characters used in the display. To change each player's "marker," change the value of A and/or B in line 160 from their current values of 86 and 102. A is the player on the left, B is on the right. Some good numbers to try are 81, 83, 87, 90, and 160.

4. To change the length of time that the final messages are displayed after each game, modify line 420. Change the 15 to 5 (or so) to shorten it, or to 30 to lengthen it.

MAIN ROUTINES

120 - 170	Initializes variables. Gets players' names. Displays titles, playing field.
180 - 200	Waits for key to be pressed to start game. Re-displays playing field.
210 - 250	Makes move for player A (on left side) and B (on right). Saves results.
255 - 350	Accepts moves from keyboard and translates direction.
400 - 490	Displays winner's name at bottom of screen. Flashes a diamond where collision occurred. Goes back to start next game.
600 - 640	Subroutine that gets each player's name.
700 - 760	Subroutine that displays winner's name.
900 - 920	Subroutine that POKE's each graphics character of each player's obstacle on the screen.
950 - 990	Subroutine that displays playing field.
1000 - 1060	Subroutine that moves marker and determines if space moved to is empty.

MAIN VARIABLES

AX,AY	Coordinates of player A's current position.
BX,BY	Coordinates of player B's current position.
A	A's marker (numeric value of graphics character).
B	B's marker.
S	Starting address of CRT memory area.
AD,BD	Current direction that A and B are going (1=up, 2=down, 3=left, 4=right).
E	Graphics character for edge of playing field.
R\$	Character being read from keyboard.
X,Y	Temporary work coordinates.
AR,BR	Result of A's and B's moves (0=okay, 1=loser).
A\$,B\$	Names of players A and B.
Z	Graphics character displayed when collision is made (must be an integer from 0 to 127).
J,K	Subscript variables.

SUGGESTED PROJECTS

1. Change the size of the playing field. The 39 in line 950 is the width, and the 22 in line 970 is the height. Note that line 160 has the starting coordinates of the two players (AX, AY, BX, and BY). You may want to change these if you make the field smaller.
2. Keep score over a seven game (or so) match. Display the current score after each game. Don't forget to allow for ties.
3. Modify the program to let each player press only two keys—one to turn left from the current direction of travel, and one to turn right.
4. Instead of a game between two people, make it a game of a person against the computer. Develop a computer strategy to keep finding open areas to move to and/or to cut off open areas from the human opponent.

ROADRACE

PURPOSE

Imagine yourself at the wheel of a high-speed race car winding your way along a treacherous course. The road curves unpredictably. To stay on course, you must steer accurately or risk collision. How far can you go in one day? How many days will it take you to race cross-country? Thrills galore without leaving your living room.

The difficulty of the game is completely under your control. By adjusting the road width and visibility conditions, ROAD-RACE can be made as easy or as challenging as you wish.

HOW TO USE IT

The program begins with a short graphics display. It then asks you for two inputs: road width and visibility. The road width (in characters) can be set anywhere between 3 and 12. The degree of difficulty changes appreciably with different widths. A very narrow setting will be quite difficult and a wide one relatively easy. Visibility can be set to any of four settings, ranging from “terrible” to “good.” When visibility is good, the car appears high on the screen. This allows a good view of the twisting road ahead. When visibility is poor, the car appears low on the screen allowing only a brief look at the upcoming road.

Having set road width and visibility, the race is ready to start. The car, represented by an asterisk (*), appears on the road at the starting line. A five-step starting light counts down the

start. When the bottom light goes on, the race begins. The road moves continually up the screen. Its twists and turns are controlled randomly. You must steer the car accurately to keep it on track.

The car is controlled with the use of two keys on the numeric keypad. Pressing the **4** will cause the car to move to the left while pressing the **6** will cause a move to the right. Doing neither will cause the car to continue straight down.

The race proceeds until the car goes "off the road." Each such collision is considered to terminate one day of the race. After each day, you are shown the number of miles achieved that day along with the cumulative miles achieved for consecutive days of the race.

After each collision, you can proceed by pressing either **C**, **R**, or **Q**. Selecting **C** will continue the race for another day with the same road conditions. Cumulative totals will be retained. **R** will restart the race. This allows changing the road conditions and initializing back to day one. **Q** simply quits the race and returns the PET back to direct Basic. Either of the last two options will produce a display of the average miles travelled per day for the race.

There are several different ways to challenge yourself with the program. You can try to see how far you get in a given number of days. You might see how many days it takes you to go a given number of miles—say 3000 miles for a cross-country trip. As you become proficient at one set of road conditions, make the road narrower and/or the visibility poorer. This will increase the challenge. Different road conditions can also be used as a handicapping aid for two unequally matched opponents.

SAMPLE RUN

The program displays its logo and begins the short input phase. The operator selects to run a course with a 6 character road width.

The operator selects fair visibility and the race is ready to begin.

The car, represented by the asterisk (*), is on the starting line. The starting light counts down the beginning of the race. When the last light goes on, the race will be off and running.

The operator, steering the car from the keyboard, finally crashes. A distance of 72 miles is obtained on this leg for a total of 242 miles in 3 days (legs). The options for continuing are displayed while the program waits for the operator's choice.

EASY CHANGES

1. The keys which cause the car to move left and right can be easily changed. You may wish to do this if you are left-handed or find that two widely separated keys would be more convenient. The changes are to be made in line 150. Left and right movements are controlled by the two string variables L\$ and R\$. If, for example, you wanted A to cause a left move and 3 to cause a right move, change line 150 to read

150 L\$="A":R\$="3"

2. The amount of windiness in the road can be adjusted by changing the value of LC in line 130. Maximum windiness is achieved with a value of 0.5 for LC. To get a straighter road,

make LC smaller. A value of 0. will produce a completely straight road. LC should lie between 0. and 0.5 or else the road will drift to one side and linger there. To get a somewhat windier road, you might change line 130 to read

130 LC=0.45:RC=1-LC

MAIN ROUTINES

120 - 170	Variable initialization.
200 - 290	Gets road conditions from user.
300 - 330	Initializes the road.
350 - 370	Determines the next road condition.
400 - 430	Updates the car position.
440 - 550	Processes end of race day.
600 - 650	Draws next road segment.
700 - 780	Graphics to begin race.
800 - 960	Initial graphics display.

MAIN VARIABLES

W	Road width.
V	Visibility.
M	Miles driven on current day.
N	Number of days of the race.
T	Total miles driven for whole race.
H	Elapsed time during race.
L\$,R\$	String characters to move car left, right.
L,R	Position of left, right side of road.
LC,RC	Random value cutoff to move road left, right.
EL,ER	Leftmost, rightmost allowable road position.
Q\$	User replies.
C	Position of car.
Z,ZC	POKE arguments for car location.
RS,LS,	Arguments of CHR\$ for road segments.
LT,RT	
B,PC	POKE arguments for graphics.
A,P	POKE arguments.
D	Array of POKE arguments for display message.
J,K,Q	Loop indices and work variables.

SUGGESTED PROJECTS

1. Write a routine to evaluate a player's performance after each collision. Display a message rating him anywhere from "expert" to "back seat driver." This should involve comparing his actual miles achieved against an expected (or average) number of miles for the given road width and visibility. For starters, you might use

$$\text{Expected miles} = W^3 + (10 * V) - 35$$

This formula is crude, at best. The coding can be done between lines 550 and 600.

2. Incorporate provisions for two players racing one at a time. Keep cumulative totals separately. After each collision, display the current leader and how far he is ahead.
3. Add physical obstacles or other hazards onto the road in order to increase the challenge. These can be done with appropriate POKE statements before the various RETURNS in lines 600-650. *Warning:* Be sure the address arguments of any POKES lie between 32768 and 33767. Anything else may result in hanging up your system. The program will recognize a collision if the car moves into any non-blank square.

WARI

PURPOSE

Wari is an old game with roots that are even older. Its origins go back thousands of years to a variety of other similar games, all classified as being members of the Mancala family. Other variations are Awari, Oware, Pallanguli, Kalah, and countless other offshoots.

The program matches you against the computer. You are probably going to lose a few games before you win one—the computer plays a pretty good game. This may hurt your ego a little bit, since Wari is purely a skill game (like chess or checkers). There is no element of luck involved, as would be the case with backgammon, for example. When you lose, it's because you were outplayed.

HOW TO USE IT

When you start the program, the first thing it does is display the Wari board and ask you if you want to go first. The board is made up of twelve squares in two rows of six. Your side is the bottom side, numbered one through six from left to right. The computer's side is on the top, numbered seven through twelve from right to left.

At the start of the game, each square has four “stones” in it. There is no way to differentiate between your stones and the computer's. They all look alike and will move from one side to the other during the course of play.

The first player “picks up” all the stones in one of the squares on his side of the board and drops them, one to a square, starting

with the next highest numbered square. The stones continue to be dropped consecutively in each square, continuing over onto the opponent's side if necessary (after square number 12 comes square number 1 again).

If the last stone is dropped onto the opponent's side *and* leaves a total of either two or three stones in that square, these stones are captured by the player who moved, and removed from the board. Also, if the next-to-last square in which a stone was dropped meets the same conditions (on the opponent's side and now with two or three stones), its stones are also captured. This continues backwards until the string of consecutive squares of two or three on the opponent's side is broken.

Regardless of whether any captures are made, play alternates back and forth between the two players.

The object of the game is to be the first player to capture twenty-four or more stones. That's half of the forty-eight stones that are on the board at the beginning of the game.

There are a few special rules to cover some situations that can come up in the game. It is not legal to capture all the stones on the opponent's side of the board, since this would leave the opponent with no moves on his next turn. By the same token, when your opponent has no stones on his side (because he had to move his last one to your side on his turn), you have to make a move that gives him at least one stone to move on his next turn, if possible. If you cannot make such a move, the game is over and counted as a draw.

During the course of the game, it's possible for a square to accumulate twelve or more stones in it. Moving from such a square causes stones to be distributed all the way around the board. When this happens, the square from which the move was made is skipped over. So, the square moved from is always left empty.

It takes the computer anywhere from five seconds to about thirty seconds to make a move, depending on the complexity of the board position. The word THINKING is displayed during this time, and a period is added to it as each possible move is evaluated in sequence (seven through twelve).

If you accidentally end the program by pressing the **RETURN** key without first entering your move, remember that you can continue the program by using Basic's **CONT** command. It's a good idea to move the cursor up a couple of lines before using this command, however, to avoid causing the screen to roll up.

SAMPLE RUN

The program starts off by drawing the playing "board" and asking who should move first. The operator decides to go first.

The program asks for the operator's move. He or she decides to move square number 5. The program alters the board accordingly, and begins "thinking" about what move to make.

Later in the same game, the computer is about to move square 12, which will capture two more stones and win the game.

```

EASY CHANGES

1. Change the length of time the ILLEGAL message is displayed after an illegal move is attempted by changing the number 3000 in line 340. Double it to double the length of time, etc.
2. Want a faster moving game against an opponent who isn't quite such a good player? Insert the following two lines:

4865 555 GOTO 600 4910
 4975 665 E(A)=V(K):GOTO 690 5000

In the standard version of the game, the computer looks at each of its possible moves and each of your possible replies when evaluating which move to make. This change causes the computer to only look at each of its moves, without bothering to look at any of your possible replies. As a result, the computer does not play as well, but it takes only a few seconds to make each move.

3. If you are curious about what the computer thinks are the relative merits of each of its possible moves, you can make this change to find out. Change line 690 so it looks like this:

5000 690 PRINT E(A);:NEXT:M=0:A=-F:FOR J=1 TO 6

This will cause the program to display its evaluation number for each of its moves in turn (starting with square seven). It will select the largest number of the six. A negative value means that it will lose stones if that move is made, assuming that you make the best reply you can. A value of negative 50 indicates an illegal move. A positive value greater than one means that a capture can be made.

MAIN ROUTINES

- | | |
|-----------|--|
| 120 - 150 | Initializes variables. Displays board. |
| 160 - 180 | Asks who goes first. Evaluates answer. |
| 190 - 220 | Determines computer's move. Displays new board position. |
| 230 - 240 | Determines if computer's move resulted in a win. Displays a message if so. |
| 250 - 300 | Gets operator's move. Checks for legality. Displays new board position. |
| 310 - 320 | Determines if operator's move resulted in a win. |

330 - 340	Displays message if illegal move attempted.
350 - 500	Subroutine to make move M in T array.
360 - 390	Copies T array into Y array (inverts if computer is making the move).
400 - 430	Makes move in Y array.
440 - 450	Checks for captures. Removes stones.
	Checks previous square.
460 - 470	Sees if opponent is left with a legal move.
480 - 500	Copies Y array back into T array.
510 - 710	Subroutine to determine computer's move.
750 - 800	Subroutine to create graphics strings for board display.
810-880	Evaluates final score. Asks about playing again.
900 - 970	Subroutine to display stones on board and captured.
990 - 1010	Subroutine to move cursor to "YOUR MOVE" position on screen.
1050	Subroutine to move cursor to "MY MOVE" position on screen.
1100 - 1110	Subroutine to backspace cursor one space and display one blank character.
1200 - 1280	Subroutine to display Wari board (without stones).
2000 - 2020	Displays messages when computer has no legal move.

MAIN VARIABLES

J,K	Subscript variables.
Q,P,F,D	Constant values of 14, 13, 50 and 12, respectively.
T,Y,W	Arrays with temporary copies of the Wari board.
V	Array with evaluation values of operator's six possible replies to computer's move being considered.
E	Array with evaluation values of computer's six possible moves.
B	Array containing Wari board. Thirteenth element has stones captured by operator. Fourteenth has computer's.
WA,WB	Weighting factors for evaluation function.
MN	Move number.

R\$	Operator's reply. Also used as switch to indicate whose move it is.
M	Move being made (1 - 6 for operator, 7 - 12 for computer). Set negative if illegal.
C	Subscript used in dropping stones around board.
L	Last square in which a stone was dropped.
S	Stones on opponent's side of the board after a move.
A	Subscript used to indicate which of the six possible computer moves is currently being evaluated.
FA	First evaluation factor used in determining favorability of board position after a move (indicates computer's number of occupied squares).
FB	Second evaluation factor (total stones on computer's side of the board).
FC	Third evaluation factor (number of squares with two or less stones).
FD	Fourth evaluation factor (number of stones in most populous square on computer's side).
FE	Total stones on board.
A\$,B\$,C\$	Strings of graphics characters used to display the Wari board.
D\$	String of thirty-two blanks.

SUGGESTED PROJECTS

1. Modify the program to declare the game a draw if neither player has made a capture in the past thirty moves. Line 300 adds one to the counter of the number of moves made. To make the change, keep track of the move number of the last capture, and compare the difference between it and the current move number with 30.
2. Modify the evaluation function used by the computer strategy to see if you can improve the quality of its play. Lines 600 through 660 examine the position of the board after the move that is being considered. Experiment with the factors and/or the weighting values, or add a new factor of your own.
3. Change the program so it can allow two people to play against each other, instead of just a person against the computer.

Section 4

Graphics Display Programs

INTRODUCTION TO GRAPHICS DISPLAY PROGRAMS

The PET is an amazing machine. It has special graphics capabilities not found on other similar computers. Programs in the other sections of this book take advantage of these graphics to facilitate and “spice up” their various output. Here we explore the use of the PET’s graphic capabilities for sheer fun, amusement, and diversion.

Ever look through a kaleidoscope and enjoy the symmetric changing patterns produced? KALEIDO will create such effects with full eight point symmetry.

Two other programs produce ever changing patterns but with much different effects. SPARKLE will fascinate you with a changing shimmering collage. SQUARES uses geometric shapes to obtain its pleasing displays.

WALLOONS demonstrates a totally different aspect of the PET’s graphic abilities. This program will keep you entertained with an example of computer animation.

KALEIDO

PURPOSE

If you have ever played with a kaleidoscope, you were probably fascinated by the endless symmetrical patterns you saw displayed. This program creates a series of kaleidoscope-like designs, with each one overlaying the previous one. The designs are symmetrical about eight axes—can you find them?

HOW TO USE IT

There is not much to say about how to use this one. Just type RUN, then sit back and watch. Turning down the lights and playing a little music is a good way to add to the effect.

By the way, it is a little misleading to say that the designs you see are symmetrical. It is more accurate to say that the positions occupied by the individual graphics characters are located symmetrically. The overall design is usually not completely symmetrical, since the individual graphics characters are not themselves symmetrical. The characters on the lower half of the design would have to be the upside-down equivalent of the corresponding characters on the upper half for that to be true.

Have a few friends bring their PETs over (all your friends *do* have PETs, don't they?), and get them all going with KALEIDO at once. Let us know if you think you have set a new world's record. Please note that we will not be responsible for any hypnotic trances induced this way.

SAMPLE RUN

One of the patterns generated by the KALEIDO program.

PROGRAM LISTING

2010 RETURN

```

EASY CHANGES

1. Change the first part of line 180 to say $D=-D$ instead of $D=1$. This will cause alternating inward and outward drawing of the designs rather than always outward from the center.
2. In line 795, change the constant of 2000 to 10000. This will cause a delay of about fifteen seconds between the drawing of successive designs instead of three seconds. Or, remove line 795 to eliminate the delay entirely.
3. Modify the range of graphics characters from which the ones in the design are randomly selected. This is done by modifying the values of M and T in lines 135 and 160. For example, try

$M = 5$ and $T = 76$
 or $M = 30$ and $T = 76$
 or $M = 12$ and $T = 116$

Experiment with other values. Be sure that M and T are both positive integers, that T is at least 65, and that the sum of M and T is no greater than 128.

4. Eliminate reverse graphics characters by deleting line 165. Or, lower the frequency of use of the reverse graphics characters by increasing the value of .5 in line 165 to, say, .8 or .9. Similarly, you can increase the frequency of use of reverse graphics characters by lowering the .5 to .1 or .2.

5. You can change the designs into ones with only four point symmetry by doing the following:

1. In lines 140 and 150, change the 6 to a 12.
2. In line 930, change the W to a J.
3. Insert this line

245 GOTO 790

MAIN ROUTINES

120 - 140	Housekeeping. Initializes variables, RND.
150 - 170	Picks seven random graphics characters.
180	Selects D, K, and L to draw patterns inward or outward.
200 - 790	Mainline routine. Determines axes of pattern.
795	Delays about three seconds after drawing design.
900 - 1020	POKEs graphics character into axes of design, then determines coordinates of points between axes.
2000 - 2010	POKEs characters between axes (subroutine).

MAIN VARIABLES

A,B	Coordinates of center of design. Upper left corner is considered to be (0,0).
S	Starting address of CRT memory map area.
D	Direction in which design is drawn (1=outward, -1=inward).
R	Array for the seven random graphics characters.
J,N	Subscript variables.
T	Numeric representation of lowest graphics character to be used.
K,L	Inner and outer bounds of design (distance from center).
X,Y	Coordinates of character being POKEd on horizontal, vertical, or diagonal axes.
X2,Y2	Coordinates of character being POKEd between horizontal, vertical, and diagonal axes.
M	Number of possible graphics characters to choose from, not counting reverses.

SUGGESTED PROJECTS

Modify the program to use the entire 40 x 25 area of the CRT screen, instead of just a 24 x 24 area in the center.

SPARKLE

PURPOSE

This graphics display program provides a continuous series of hypnotic patterns, some of which seem to sparkle at you while they are created. Two types of patterns are used. The first is a set of concentric diamond shapes in the center of the screen. Although the pattern is regular, the sequence in which it is created is random, which results in the “sparkle” effect.

The second type of pattern starts about two seconds after the first has finished. It is a series of “sweeps” across the screen—left to right and top to bottom. Each sweep uses a random graphics character that is spaced equally across the screen. The spacing distance is chosen at random for each sweep. Also, the number of sweeps to be made is chosen at random each time in the range from 10 to 30.

After the second type of pattern is complete, the program goes back to the first type, which begins to overlay the center of the second type.

HOW TO USE IT

Confused by what you just read? Never mind. You have to see it to appreciate it. Just enter the program into your PET, then sit back and watch the results of your labor.

SAMPLE RUN

One of the patterns generated by the SPARKLE program.

PROGRAM LISTING

```

280 X=A+W:Y=B+R:GOSUB 900
290 Y=B-R:GOSUB 900
300 X=A-W:GOSUB 900

```

```

310 Y=B+R:GOSUB 900
320 NEXT: NEXT
350 FOR J=1 TO 2000: NEXT
400 N=65:M=63
410 FOR J=1 TO INT(21*RND(1))+10
420 R=INT(22*RND(1))+1:W=INT(M*RND(1))
430 T=S:IF RND(1)>.8 THEN T=T+1
440 POKE S,N+W
450 FOR K=T TO T+999 STEP R
460 POKE K,N+W:NEXT
470 NEXT
480 GOTO 140
900 POKE S+40*Y+X,C
910 RETURN

```

EASY CHANGES

1. Make the second type of pattern appear first by inserting this line:

135 GOTO 400

Or, eliminate the first type of pattern by inserting:

145 GOTO 400

Or, eliminate the second type of pattern by inserting:

360 GOTO 140

2. Increase the delay after the first type of pattern by increasing the 2000 in line 350 to, say, 5000. Remove line 350 to eliminate the delay.
3. Increase the number of sweeps across the screen of the second type of pattern by changing the 10 at the right end of line 410 into a 30 or a 50, for example. Decrease the number of sweeps by changing the 10 to a 1, and also changing the 21 in line 410 to 5 or 10.
4. Watch the effect on the second type of pattern if you change the 22 in line 420 into various integer values between 2 and 100.
5. Change the values of N and M in line 400 to alter the graphics characters used in the second type of pattern. For example, try

N=76 and M=5

or, N=120 and M=8

Be sure that N is at least 65, and the sum of N and M is no more than 128.

MAIN ROUTINES

120 - 130	Initializes variables. Clears screen.
140 - 320	Displays square pattern in center of screen.
150 - 190	Shuffles the numbers 0 through 12 in the A and B arrays.
200 - 320	POKEs graphics characters to the screen.
350	Delays for about 2 seconds.
400 - 480	Overlays the entire screen with a random graphics character spaced at a fixed interval chosen at random.
900 - 910	Subroutine to POKE graphics character C to location (X,Y). Upper left corner of screen is location (0,0).

MAIN VARIABLES

R	Random integer. Also, work variable.
A,B	Arrays in which shuffled integers from 0 to 12 are stored for use in making first type of pattern.
A,B	Coordinates of center of screen (19 across, 12 down).
S	Address of beginning of screen.
T	Integer from 66 to 102, used in creating random graphics characters. Also, work variable.
J,K	Work and loop variables.
W	Work variable.
X,Y	Coordinates of a position on the screen for a graphics character.
C	Graphics character to be POKEd to screen at X,Y.
N	Lowest graphics character to be used in second type of pattern.
M	Multiplier used in getting a random integer to add to N.

SUGGESTED PROJECTS

Make the second type of pattern alternate between “falling from the top” (as it does now) and rising from the bottom of the screen.

SQUARES

PURPOSE

This is another graphics-display program. It draws a series of concentric squares, with the graphics character used for each square chosen at random. After a full set of concentric squares is drawn, the next set starts again at the center and overlays the previous one. The speed at which each set of squares is drawn fluctuates to provide another dimension to the designs.

HOW TO USE IT

As with most of the other graphics display programs, you just sit back and enjoy watching this one once you get it started.

SAMPLE RUN

One of the patterns generated by the SQUARES program.

PROGRAM LISTING

```

100 REM: SQUARES
110 REM: COPYRIGHT 1978 BY TOM RUGG AND PHIL FELDMAN
120 J=RND(-TI):PRINT CHR$(147)
130 GOSUB 600:N=1:R=INT(50*RND(1))
140 C=INT(95*RND(1))+160
150 PRINT CHR$(146);
160 IF RND(1)>.5 THEN PRINT CHR$(18);
170 X=C:Y=0:K=N:GOSUB 700
180 N=N+1
190 Y=145:Z=157:K=N:GOSUB 800
200 Y=157:GOSUB 800
210 N=N+1
220 Y=17:K=N:GOSUB 800
230 IF N<22 THEN 140
240 GOTO 130
600 K=11:X=29:Y=29:Z=17
610 PRINT CHR$(19):GOSUB 800:RETURN
700 FOR J=1 TO K:GOSUB 900

```

```
710 PRINT CHR$(X);CHR$(Y);:NEXT:RETURN
800 FOR J=1 TO K:GOSUB 900
810 PRINT CHR$(X);CHR$(Y);CHR$(Z);
820 NEXT:RETURN
900 FOR W=1 TO R:NEXT:RETURN
```

EASY CHANGES

1. To eliminate the variable speed feature of the program, insert this line:

135 R=25

This will cause the speed to be fixed at about the level of the average speed when the variable speed feature is active. Instead of 25, try 1 for high speed, or 50 or 100 for low speed.

2. To eliminate the use of reverse graphics characters in the display, remove line 160.
3. To make the patterns less regular, try inserting these lines:

```
802 D=0:IF INT(J/2)=J/2 THEN D=1
804 X=X+D
815 X=X-D
```

MAIN ROUTINES

- | | |
|-----------|--|
| 120 - 130 | Initializes variables. Clears screen. Determines speed for this set of squares. |
| 140 - 160 | Picks random graphics character. |
| 170 - 220 | Mainline routine. Draws a square using cursor control characters. |
| 230 - 240 | Determines if set of squares is done. If so, starts over. If not, draws next square. |
| 600 - 610 | Subroutine to move cursor to center of screen. |
| 700 - 710 | Subroutine to do K repetitions of printing CHR\$ of X and Y. |
| 800 - 820 | Subroutine to do K repetitions of printing CHR\$ of X, Y, and Z. |
| 900 | Delay subroutine. |

MAIN VARIABLES

J,K,W	Work and loop variables.
N	Length of the side of the square being drawn.
R	Random number from 0 to 49 for time delay.
C	ASCII value of graphics character.
X,Y,Z	ASCII values of characters being printed by sub-routines. Can be cursor control characters or graphics characters.

WALLOONS

PURPOSE

The PET is quite a versatile machine. This program takes advantage of its powerful graphics capability to produce computer animation. That's right, animation! WALLOONS will entertain you with a presentation from the Pet Playhouse.

The Pet Playhouse searches the world over to bring you the best in circus acts and other performing artists. Today, direct from their performance before the uncrowned heads of Europe, the Playhouse brings you the Flying Walloons.

HOW TO USE IT

Just sit back, relax, and get ready to enjoy the show. Type RUN and the Flying Walloons will be ready to perform. You have a front row center seat and the curtain is about to go up.

Applause might be appropriate if you enjoy their performance. Please note that the Walloons have been working on a big new finish to their act which they haven't yet quite perfected.

SAMPLE RUN

The billboard announces a new presentation of the (in)famous PET Playhouse.

"The Flying Walloons" are to perform!

The walloons attempt a dangerous trick from their repertoire.

EASY CHANGES

1. If you wish to have the Walloons perform more (or less) jumps during their performance, change the value of NJ in line 150 accordingly. To get five jumps, use

150 NJ=5

2. Timing delays are used often in the program. To change the length of the delay, alter the 1000 in line 1920 to a different value. Values larger than 1000 will lengthen the delays, while values smaller than 1000 will shorten the delays.
3. You might want to personalize the title placard and make yourself the presenter of the Walloons. This can be done by altering the string literal, "PET PLAYHOUSE" in line 270 to something else. However, you cannot use a string with a length of much more than 14 characters or it will print beyond the end of the placard. To say, for example, that Simon Fenster presents the Walloons, change line 270 to:

270 PRINT TAB(13);"SIMON FENSTER":PRINT

MAIN ROUTINES

150	Sets NJ.
200 - 290	Displays title placard.
400 - 470	Removes "proudly," displays rest of title.
500 - 530	Moves first Walloon into view.
600 - 760	Second Walloon enters from the high platform.
800 - 980	Flying Walloons perform.
1000 - 1110	Concludes Walloon's performance.
1600 - 1670	Subroutine to draw lever with right side down.
1700 - 1760	Subroutine to draw lever with right side up.
1800 - 1820	Subroutine to draw Walloon with head at Poke location A.
1850 - 1870	Subroutine to erase Walloon with head at A.
1900	Subroutine to clear screen.
1920	Time delaying subroutine.

MAIN VARIABLES

NJ	Number of jumps to make.
A	Reference Poke location.
R	Jump Counter.
J,K,L,Q	Loop Indices.

SUGGESTED PROJECTS

1. There are many possibilities for "spicing up" the Walloons' act with extra tricks or improved ones. Perhaps you would like to change their finish to something less crude. To get you started, here are the changes to produce one alternate ending:

```

1000 GOTO 1200
1200 FOR A=32832 TO 32472 STEP -40
1210 GOSUB 1800:GOSUB 1850:NEXT
1220 GOSUB 1920:GOSUB 1900:GOTO 1090

```

One word of warning about this new coding. It intentionally does some POKes to addresses that are non-functioning on 4K and 8K PETs. This could cause problems only if you have expanded your user memory up to a full 32K.

2. If you add some alternate tricks or endings as suggested in the previous project, try randomizing if and when they will

be done. Thus, the Walloons' performance will be different each time the program is run. At least their ending may be variable.

3. Scour the world yourself for other acts to include in the Pet Playhouse. Maybe someday we will have a complete software library of performing artists.

Section 5

Mathematics Programs

INTRODUCTION TO MATHEMATICS PROGRAMS

Since their invention, computers have been used to solve mathematical problems. Their great speed and reliability render solvable many otherwise difficult (or impossible) calculations. Several different numerical techniques lend themselves naturally to computer solution. The following programs explore some of them. They will be of interest mainly to engineers, students, mathematicians, statisticians, and others who encounter such problems in their work.

GRAPH takes advantage of the PET's graphic powers to draw the graph of a function $Y = f(X)$. The function is supplied by you. INTEGRATE calculates the integral, or "area under the curve," for any such function.

Experimental scientific work frequently results in data at discrete values of X and Y . CURVE finds a polynomial algebraic expression to express this data with a formula.

Theoretical scientists (and algebra students) often must find the solution to a set of simultaneous linear algebraic equations. SIMEQN does the trick.

Much modern engineering work requires the solution of differential equations. DIFFEQN will solve any first-order ordinary differential equation that you provide.

STATS will take a list of data and derive standard statistical information describing it. In addition, it will sort the data list into ranking numerical order.

CURVE

PURPOSE AND DISCUSSION

CURVE fits a polynomial function to a set of data. The data must be in the form of pairs of X-Y points. This type of data occurs frequently as the result of some experiment, or perhaps from sampling tabular data in a reference book.

There are many reasons why you might want an analytic formula to express the functional relationship inherent in the data. Often you will have experimental errors in the Y values. A good formula expression tends to smooth out these fluctuations. Perhaps you want to know the value of Y at some X not obtained exactly in the experiment. This may be a point between known X values (interpolation) or one outside the experimental range (extrapolation). If you wish to use the data in a computer program, a good formula is a convenient and efficient way to do it.

This program fits a curve of the form

$$Y = C_0 + C_1 X^1 + C_2 X^2 + \dots + C_D X^D$$

to your data. You may select D, the degree (or power) of the highest term, to be as large as 9. The constant coefficients, $C_0 - C_D$, are the main output of the program. Also calculated is the goodness of fit, a guide to the accuracy of the fit. You may fit different degree polynomials to the same data and also ask to have Y calculated for specific values of X.

The numerical technique involved in the computation is known as least squares curve fitting. It minimizes the sum of the squares of the errors. The least squares method reduces the

problem to a set of simultaneous algebraic equations. Thus these equations could be solved by the algorithm used in SIMEQN. In fact, once the proper equations are set up, CURVE uses the identical subroutine found in SIMEQN to solve the equations. For more information, the bibliography contains references to descriptions of the numerical technique.

HOW TO USE IT

The first thing you must do, of course, is enter the data into the program. This consists of typing in the pairs of numbers. Each pair represents an X value and its corresponding Y value. The two numbers (of each pair) are separated by a comma. A question mark will prompt you for each data pair. After you have entered them all, type

999,999

to signal the end of the data. When you do this, the program will respond by indicating how many data pairs have been entered. A maximum of 100 data pairs is allowed.

Next, you must input the degree of the polynomial to be fitted. This can be any non-negative integer subject to certain constraints. The maximum allowed is 9. Unless your data is well behaved (X and Y values close to 1), the program will often not produce accurate results if D is greater than 5 or so. This is because sums of powers of X and Y are calculated up to powers of 2^D . These various sums are several orders of magnitude different than each other. Errors result because of the numerous truncation and round-off operations involved in doing arithmetic with them. Also, D must be less than the number of data pairs. You will get an error message if you input an illegal value of D.

A few notes regarding the selection of D may be of interest. If $D=0$, the program will output the mean value of Y as the coefficient C_0 . If $D=1$, the program will be calculating the best straight line through the data. This special case is known as "linear regression." If D is one less than the number of data pairs, the program will find an exact fit to the data (barring round-off and other numerical errors). This is a solution which passes exactly through each data point.

Once you have entered the desired degree, the program will begin calculating the results. There will be a pause while this

calculation is performed. The time involved depends on the number of data pairs and the degree selected. For twenty-five data pairs and a third degree fit, the pause will be about half a minute. Fifty data pairs and a fifth degree fit will take about a minute.

The results are displayed in a table. It gives the values of the coefficients for each power of X from 0 to D. That is, the values of $C_0 - C_D$ are output. Also shown is the percent goodness of fit. This is a measure of how accurately the program was able to fit the given case. A value of 100 percent means perfect fit, lesser values indicate correspondingly poorer fits. It is hard to say what value denotes *satisfactory* fit since much depends on the accuracy of data and the purpose at hand. But as a rule of thumb, anything in the high nineties is quite good. For those interested, the formula to calculate the percent goodness of fit is

$$P.G.F = 100 * \sqrt{1 - \frac{\sum_i (Y_i - \hat{Y}_i)^2}{\sum_i (Y_i - \bar{Y})^2}}$$

where Y_i are the actual Y data values, \hat{Y}_i are the calculated Y values (through the polynomial expression), and \bar{Y} is the mean value of Y.

Next, you are presented with three options for continuing the run. These are 1) determining specific points, 2) fitting another degree, 3) ending the program. Simply type 1, 2, or 3 to make your selection. A description of each choice now follows.

Option 1 allows you to see the value of Y that the current fit will produce for a given value of X. In this mode you are continually prompted to supply any value of X. The program then shows what the polynomial expression produces as the value for Y. Input 999 for an X value to leave this mode.

Option 2 allows you to fit another degree polynomial to the same data. Frequently, you will want to try successively higher values of D to improve the goodness of fit. Unless round-off errors occur, this will cause the percent goodness of fit to increase.

Option 3 simply terminates the program and with that we will terminate this explanation of how to use CURVE.

SAMPLE PROBLEM AND RUN

Problem: An art investor is considering the purchase of Primo's masterpiece, "Frosted Fantasy." Since 1940, the painting has been for sale at auction seven times. Here is the painting's sales record from these auctions.

<u>Year</u>	<u>Price</u>
1940	\$ 8000.
1948	\$13000.
1951	\$16000.
1956	\$20000.
1962	\$28000.
1968	\$39000.
1975	\$53000.

The painting is going to be sold at auction in 1979. What price should the investor expect to have to pay to purchase the painting? If he resold it in 1983, how much profit should he expect to make?

Solution: The investor will try to get a polynomial function that expresses the value of the painting as a function of the year. This is suitable for CURVE. The year will be represented by the variable X, and the price is shown by the variable Y. To keep the magnitude of the numbers small, the years will be expressed as elapsed years since 1900, and the price will be in units of \$1000. (Thus a year of 40 represents 1940, a price of 8 represents \$8000.)

SAMPLE RUN

READY.

Initially, a first degree fit was tried and a goodness of fit of about 97.5% was obtained. The investor wanted to do better, so he tried a second degree fit next. This had a very high goodness of fit. He then asked for the extrapolation of his data to the years 1979 and 1983. He found that he should expect to pay about \$62250 to buy the painting in 1979. Around a \$10000 profit could be expected upon resale in 1983.

Of course, the investor did not make his decision solely on the basis of this program. He used it only as one guide to his decision. There is never any guarantee that financial data will perform in the future as it has done in the past. Though CURVE is probably as good a way as any, extrapolation of data can never be a totally reliable process.

EASY CHANGES

1. The program uses 999 as the flag number to terminate various input modes. This may cause a problem if your data include 999. You can easily change the flag number by modifying the value of EF in line 160 to any value not needed in your data. To use 10101, for example, make this change:

160 EF=10101

2. Currently, a maximum value of 100 data pairs is allowed. If you need more, change the value of MX in line 150 to the number required. However, you cannot set MX to anything higher than 255. To achieve this absolute maximum, make this change:

150 MX=255

3. To allow fits of higher degrees than 9, set MD in line 170 to the maximum degree desired. A value of 14 is the absolute limit. To achieve this, use

170 MD=14

However, it must be stressed that the program will generally be quite unreliable for these high degrees. A practical limit for MD is 7.

4. The current dimensioning requires a PET with 8K of memory. To operate the program with a 4K PET, make these changes:

150 MX=20

170 MD=4

This will mean, of course, that you will be restricted to using twenty data pairs and fourth degree fits.

MAIN ROUTINES

150 - 170	Initializes constants.
200 - 220	Dimensions arrays.
300 - 380	Displays introductory messages.
400 - 470	Gets X-Y input data from the user.
500 - 550	Gets degree of polynomial from the user, determines if it is acceptable.
600 - 670	Sets up equations for the simultaneous equation solver and calls it.
700 - 780	Calculates percent goodness of fit, displays all results.
800 - 860	Gets user's continuation option and branches to it.
900 - 940	Determines Y value corresponding to any X value.
2000 - 2180	Subroutine to solve simultaneous linear algebraic equations.

MAIN VARIABLES

MX	Maximum number of data pairs allowed.
MD	Maximum degree allowed to fit.
EF	Ending flag value for data input and X point mode.
X,Y	Arrays of X and Y data points.
NP	Number of data pairs entered.
D	Degree of polynomial to fit.
D2	2*D, the maximum power sum to compute.
N	D+1, number of simultaneous equations to solve.
A,R,V	Arrays for simultaneous linear equation solver.
P	Array for holding sums of various powers of X.
I,J,K,L	Loop indices.
Q,G	Work variables.
M	Mean value of Y.
T	Percent goodness of fit.

XV	Specific X point to calculate Y for.
YV	Y value corresponding to XV.

SUGGESTED PROJECTS

1. No provision for modifying the data is incorporated into the program. Often it would be nice to add, subtract, or modify parts of the data after some results are seen. Build in a capability to do this.
2. You may desire other forms of output. A useful table for many applications might include the actual X values, calculated Y values, and/or percentage errors in Y.
3. Sometimes certain points (or certain regions of points) are known to be more accurate than others. Then you would like to weight these points as being more important than others to be fit correctly. The least squares method can be modified to include such a weighting parameter with each data pair. Research this technique and incorporate it into the program. (Note: you can achieve some weighting with the current program by entering important points two or more times. There is a certain danger in this, however, You must only ask for a solution with D less than the number of *unique* data points. A division by zero error may result otherwise.)
4. Often you wish to try successively higher degree polynomials until a certain minimum percent goodness of fit is obtained. Modify the program to accept a minimally satisfactory percent goodness of fit from the user. Then have the program automatically try various polynomial fits until it finds the lowest degree fit, if any, with a satisfactory goodness of fit.

DIFFEQN

PURPOSE

Differential equations express functions by giving the rate of change of one variable with respect to another. This type of relation occurs regularly in almost all the physical sciences. The solution of these equations is necessary in many practical engineering problems.

For many such equations, a closed form (or exact analytical expression) solution can be obtained. However, for just as many, no such “simple” solution exists. The equation must then be solved numerically, usually by a computer program such as this.

There are many types and classes of differential equations. This program solves those of a simple type; namely, first order, ordinary differential equations. This means the equation to be solved can be written in the form

$$\frac{dY}{dX} = (\text{any function of } X, Y)$$

Here, X is the independent variable and Y is the dependent variable. The equation expresses the derivative (or rate of change) of Y with respect to X. The right-hand-side is an expression which may involve X and/or Y.

To use the program, you must supply it with the differential equation to be solved. The procedure to do this is explained in the “How To Use It” section.

A technique known as the “fourth-order, Runge-Kutta” method is used to solve the equation. Space limitations prevent

any detailed explanation of it here. However, it is discussed well in the numerical analysis books referenced in the bibliography.

The program allows two forms of output. You can have the answers tabulated in columns or plotted graphically.

HOW TO USE IT

The first thing you must do is enter the differential equation into the program. This must be done at line 3000. Currently this line contains a GOTO statement. This will cause an error message to be displayed if the program is run before you have changed line 3000. The form of line 3000 should be:

3000 D = (your function of X,Y)

D represents dY/dX . GOSUBs are made to line 3000 with X and Y set to their current values. Thus, when each RETURN is made, D will be set to the appropriate value of dY/dX for that given X and Y. If necessary, you may use the lines between 3000 and 3999 to complete the definition of D. Line 3999 already contains a RETURN statement so you do not need to add another one.

The program begins by warning you that you should have already entered the equation at line 3000. You acknowledge that this has been done by hitting the C key to continue.

Now the various initial conditions are input. You are prompted for them one at a time. They consist of: the initial values of X and Y, the stepsize interval in X at which to display the output, and the final value of X.

You now have a choice between two types of output. Enter a T for tabular output or a G for graphical output. The tabular form is simply a two column display of the corresponding values of X and Y.

The graphical output plots the values of Y along a horizontal axis as each corresponding X value is displayed on successive lines of the screen. This graphical display requires you to input the minimum and maximum values of Y that will be used on the Y axis. You will be prompted for them if this output form is chosen. An open circle is used to plot the value of Y. If, however, the value of Y is "off-scale," a closed circle is plotted at the appropriate edge of the graph.

With the input phase completed, the program initializes things to begin the output. A question mark will be displayed in the

lower left of the screen, telling you the program is waiting for you to hit any key to begin the output.

The output is displayed at each interval of the stepsize until the final value of X is reached. Output may temporarily be halted at any time by simply hitting any key. This will stop the display until you hit any key to resume the output. The output may be started and stopped as often as desired, thus enabling you to leisurely view intermediate results before they scroll off the screen. It is applicable to both the tabular and graphical forms of output.

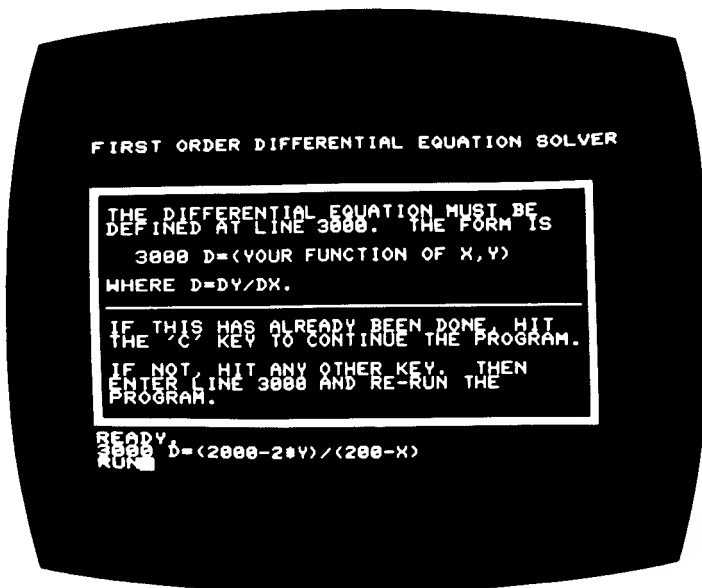

SAMPLE PROBLEM AND RUN

Problem: A body, originally at rest, is subjected to a force of 2000 dynes. Its initial mass is 200 grams. However, while it moves, it loses mass at the rate of 1 gram/sec. There is also an air resistance equal to twice its velocity retarding its movement. The differential equation expressing this motion is:

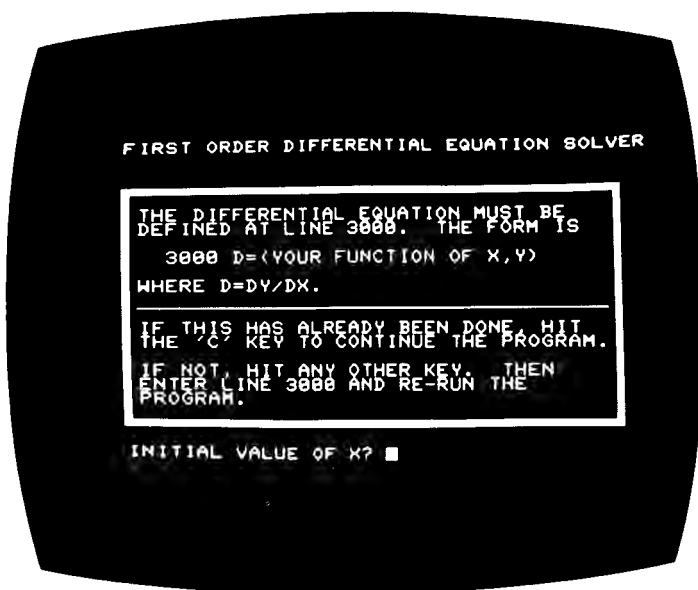

$$\frac{dY}{dX} = \frac{(2000 - 2Y)}{(200 - X)} \quad \begin{array}{l} \text{where } Y=\text{velocity (cm./sec.)} \\ X=\text{time (sec.)} \end{array}$$

Find the velocity of the body every 10 seconds up through two and a half minutes. Also, plot this velocity as a function of time.

Solution and Sample Run: The solution and sample run are illustrated in the accompanying photographs.

The operator hits a key to exit from the program. Then he enters the differential equation into line 3000. He types RUN to restart the program.

The operator has hit the "C" key. The program responds by beginning the input phase.

```

INITIAL VALUE OF X? 0
INITIAL VALUE OF Y? 0
STEPSIZE IN X? 10
FINAL VALUE OF X? 150
OUTPUT FORM (T=TABLE, G=GRAPH)? T

```

THE FOLLOWING OUTPUT CAN BE HALTED
BY HITTING ANY KEY. IT CAN THEN BE
RESUMED BY HITTING ANY KEY. THIS MAY
BE DONE AS OFTEN AS DESIRED.

WHEN THE QUESTION MARK (?) APPEARS,
HIT ANY KEY TO BEGIN THE OUTPUT.

	<u>X</u>	<u>Y</u>
?		

The operator has completed the input and requested tabular output. The program signals with a question mark that it is waiting for him to hit any key. It will not continue the run until he does so.

HIT ANY KEY TO BEGIN THE OUTPUT.

<u>X</u>	<u>Y</u>
0	0
10	10
20	40
30	90
40	160
50	250
60	360
70	490
80	640
90	810
100	1000
110	1210
120	1440
130	1690
140	1960
150	2250

READY.

The operator hits a key and the program responds with the tabulated output. X is time in seconds and Y is velocity in cm./sec.

The program is rerun requesting graphical output. Before this photo, the program requested a minimum and maximum value of Y to use on the Y axis. Values of 0 and 1000 respectively were entered. The program displays the desired graph.

```

EASY CHANGES

1. If you have already entered the differential equation and wish to skip the introductory output, add this line:

225 GOTO 410

This will immediately begin the input dialog.

2. If you wish to use negative stepsizes, line 900 must be changed to:

900 Q=XX+DX:IF Q<XF-1.E-5 THEN END

MAIN ROUTINES

200 - 380	Displays initial messages.
390 - 520	Gets user's inputs.
600 - 670	Displays additional messages.
700 - 750	Initializes output display.
800 - 830	Waits for user to hit a key to start the output.
900 - 960	Computes each step.

1000 - 1030 Error message.
 1500 - 1550 Plots graphical output.
 1600 - 1620 Stops and starts output.
 3000 - 3999 User supplied routine to define D.

MAIN VARIABLES

D	Value of dY/dX .
X,Y	Values of X,Y on current step.
XX,YY	Values of X,Y on last step.
DX	Stepsize in X.
XF	Final value of X.
F\$	Output flag string (T=table, G=graph).
YL,YH	Minimum, maximum values of Y plot axis.
V	Tab position for graphical output.
C	CHR\$ argument for graphical output.
K0,K1, K2,K3	Runge-Kutta coefficients.
R\$	User entered string.
Q	Work variable.
J	Loop index.

SUGGESTED PROJECTS

1. Modify the program to display the tabular output followed by the graphical output. During the tabular phase, the minimum and maximum values of Y can be saved and automatically used as the plot limits for the graphical output.
2. The value of dY/dX as a function of X is often a useful quantity to know. Modify the program to add it to the columnar display and/or the graphical display.
3. The inherent error in the calculation depends on the stepsize chosen. Most cases should be run with different stepsizes to insure the errors are not large. If the answers do not change much, you can be reasonably certain that your solutions are accurate. Better yet, techniques exist to vary the stepsize during the calculation to insure the error is sufficiently small during each step. Research these methods and incorporate them into the program.
4. The program can be easily broadened to solve a set of coupled, first order, differential equations simultaneously. This would

greatly increase the types of problems that could be solved. Research this procedure and expand the program to handle it.

GRAPH

PURPOSE

Is a picture worth a thousand words? In the case of mathematical functions, the answer is often "yes." A picture, i.e. a graph, enables you to see the important behavior of a function quickly and accurately. Trends, minima, maxima, etc. become easy and convenient to determine.

GRAPH produces a two-dimensional plot of a function that you supply. The function must be in the form $Y = (\text{any function of } X)$. The independent variable X will be plotted along the abscissa (horizontal axis). The dependent variable Y will be plotted along the ordinate (vertical axis). You have complete control over the scaling that is used on the X and Y axes.

The program uses a special "double precision" graphing technique which doubles the normal resolution of the PET's graphics.

HOW TO USE IT

Before running the program, you must enter into it the function to be plotted. This is done as a subroutine beginning at line 5000. It must define Y as a function of X . The subroutine will be called with X set to various values. It must then set the variable Y to the correct corresponding value. The subroutine may be as simple or as complex as necessary to define the function. It can take one line or several hundred lines. Line 5999 is already set as a RETURN statement, so you need not add another one.

Having entered this subroutine, you are ready to run the program. The program begins by warning you that it assumes the function has already been entered at line 5000. It will then ask you for the domain of X, i.e. the lowest and highest values of X that you wish to have plotted. Values can be positive or negative as long as the highest value is actually larger than the lowest one.

Now you must choose the scale for Y. To do this intelligently, you probably need to know the minimum and maximum values of Y over the domain of X selected. The program finds these values and displays them for you. You must then choose the minimum and maximum values you wish to have on the Y scale. Again, any two values are acceptable as long as the maximum scale value of Y is larger than the minimum scale value of Y.

The program will now display the plot of your function. Each axis is twenty characters long, with the origin defined as the minimum scale values of both X and Y. Twenty tick marks appear on each axis. The minimum, middle, and maximum values on each scale are displayed appropriately. (Note: the program may not be able to display all six scaling numbers if you input some scaling numbers having a large number of significant digits. If this occurs on the X axis, the program may use one or more of the expressions "XL," "XM," or "XU" instead of the actual numbers. These stand respectively for "X lower," "X mid," and "X upper." Similarly, "YL," "YM," or "YU" may be used on the Y axis.)

The actual plot is drawn with twice the resolution shown on the axes. That is, forty values of X and Y are plotted. This is accomplished by using the various 2 by 2 graphic characters available on the PET.

If a value for Y should be off-scale, a special shaded character will be displayed at the appropriate value of X. If the actual value of Y is too large, it will be plotted at the maximum Y value. Similarly, it will be drawn at the minimum Y value if it is too low.

After the plot is drawn, the program will tell you to hit any key to continue. When you do so, information about the plot scaling is provided. For both X and Y, you are given the minimum, mid, and maximum values on each axis. Also displayed is the value corresponding to one tick mark on each axis.

You now have the option of hitting G to draw the graph again or any other key to terminate the program.

SAMPLE RUN

After loading the program, the operator enters line 5000 to request the graph $Y=\sin(X)$. RUN is typed to begin the program.

The input dialog transpires. The operator asks that the domain of X be 0-6.28. The program responds by showing the maximum and minimum value of Y over this domain. The operator chooses an appropriate scale for the Y axis.

The graph is displayed as requested. The program waits for the operator to hit any key to continue.

Relevant scaling information is shown. By pressing "G", the operator can see the graph again.

EASY CHANGES

1. You may want the program to self-scale the Y axis for you. That is, you want it to use the minimum and maximum Y values that it finds as the limits on the Y axis. This can be accomplished by adding the following line:

```
835 YU=MX:YL=MN:RETURN
```

2. Do you sometimes forget to enter the subroutine at line 5000 despite the introductory warning? As is, the program will plot the straight line $Y=0$ if you do this. If you want a more drastic reaction to prevent this, change line 5000 to read

```
5000 Y=1/0
```

Now, if you don't enter the actual subroutine desired, the program will stop and print the following message after you enter the X scaling values.

?DIVISION BY ZERO ERROR IN 5000

3. Would you like something different to be displayed as the off-axis character? This can be done by changing the value of PB in line 160. The following table shows the correspondence between PB and the character used.

<u>PB</u>	<u>CHARACTER</u>
81	●
86	×
90	◆
160	■

For example, to have a diamond drawn as the off-axis character, change line 160 to be:

160 PB=90

MAIN ROUTINES

150 - 170	Initializes constants.
200 - 210	Displays introductory warning.
220 - 280	Mainline routine—gets X scaling from user and calls various subroutines.
300 - 480	Subroutines to draw graph axes and scale labelling.
500 - 670	Subroutine to plot the function.
700 - 740	Subroutine to determine the plotting position for Y.
800 - 880	Subroutine which determines the minimum, maximum Y values; gets Y scale from user.
900 - 980	Subroutine which displays the scaling parameters, asks user if he wants the graph re-plotted.
1000 - 1100	Subroutines to display the introductory warning.
5000 - 5999	User supplied subroutine to evaluate Y as a function of X.

MAIN VARIABLES

XL,XM,	Lower, middle, upper scale values of X.
XU	
YL,YM,	Lower, middle, upper scale values of Y.
YU	
DX,DY	Scale increments of X,Y.
X,Y	Current values of X,Y.
C	Poke argument for the plot origin.
PC	Poke argument for normal plotting.
PB	Poke argument for off-axis plotting.
PK	Peek value.
W	CHR\$ argument.
TB,XV	Tab arguments.

F	Y position flag (0=down, 1=up).
V	Value of X or Y in scale units.
D	Integer value of V.
MN,MX	Minimum, maximum values of Y.
A\$	String representation of axis numbers.
A	Length of A\$.
NL	Number of lines to print.
Q\$	User reply string.
J	Loop index.

SUGGESTED PROJECTS

1. Determine and display the values of X at which the minimum and maximum values of Y occur.
2. After the graph is plotted, allow the user to obtain the exact value of Y for any given X.
3. Expand the graph to a 30 character width in the X direction.

INTEGRATE

PURPOSE AND DEFINITION

The need to evaluate integrals occurs frequently in much scientific and mathematical work. This program will numerically integrate a function that you supply using a technique known as Simpson's rule. It will continue to grind out successive approximations of the integral until you are satisfied with the accuracy of the solution.

Mathematical integration will probably be a familiar term to those who have studied some higher mathematics. It is a fundamental subject of second-year calculus. The integral of a function between the limits $x=l$ (lower limit) and $x=u$ (upper limit) represents the area under its curve; i.e. the shaded area in Figure 1.

We may approximate the integral by first dividing up the area into rectangular strips or segments. We can get a good estimate of the total integral by summing the areas of these segments by using a parabolic fit across the top. For those who understand some mathematical theory, Simpson's rule may be expressed as

$$\int_{x=l}^{x=u} f(x) dx \cong \frac{\Delta}{3} \left\{ f(l) + f(u) + 4 \sum_{j=1}^{N/2} f[l + \Delta(2j-1)] + 2 \sum_{j=1}^{(N-2)/2} f[l + 2\Delta j] \right\}$$

Figure 1. The Integral of $f(x)$

Here N is the number of segments into which the total interval is divided. N is 4 in the diagram.

For a good discussion of the numerical evaluation of integrals see: McCracken, Dorn, *Numerical Methods and Fortran Programming*, New York, Wiley, 1964, pp.160. Don't let the word "Fortran" scare you away. The discussions in the book are independent of programming language with only some program examples written in Fortran.

HOW TO USE IT

The program begins with a warning! This is to remind you that you should have already entered the subroutine to evaluate Y as a function of X . This subroutine must start at line 5000. More about it shortly.

You will then be asked to provide the lower and upper limits of the integration domain. Any numerical values are acceptable.

It is not even necessary that the lower limit of X be smaller than the upper one.

The program will now begin displaying its numerical evaluations of the integral. The number of segments used in the calculation continually doubles. This causes the accuracy of the integral to increase at the expense of additional computation time. For most functions, you should see the value of the integral converging quickly to a constant (or near constant) value. This, of course, will be the best numerical evaluation of the integral at hand.

When you are satisfied with the accuracy of the solution, you must hit the **STOP** key to terminate the program. If not, the program will run forever (assuming you can pay the electric bills). The amount of computation is approximately doubled each step. This means it will take the computer about the same amount of time to compute the next step that it took to compute *all* the previous steps. Thus, it will soon be taking the PET hours, days, and weeks to compute steps. Eventually, round-off errors begin degrading the results, causing a nice, constant, converged solution to change. However, the high precision of the PET's floating point arithmetic will postpone this for quite a while. You will probably lose patience before seeing it.

The function to be integrated can be as simple or as complicated as you desire. It may take one line or a few hundred lines of code. In any case, the subroutine to express it must start at line 5000. This subroutine will be continually called with the variable X set. When it returns, it should have set the variable Y to the corresponding value of the function for the given X . The subroutine must be able to evaluate the function at any value of X between the lower and upper bounds of the integration domain.

If your function consists of experimental data at discrete values of X , you must do something to enable the subroutine to evaluate the function at intermediate values of X . We recommend one of two approaches. First, you could write the subroutine to linearly interpolate the value of Y between the appropriate values of X . This will involve searching your data table for the pair of experimental X values that bound the value of X where the function is to be evaluated. Secondly, the program **CURVE** presented elsewhere in this section can produce an approximate polynomial expression to fit your experimental data. This

expression can then be easily entered as the subroutine at line 5000.

By the way, Simpson's rule is *exact* for any polynomial of degree 3 or less. This means that if the function can be written in the form

$$Y = A * X^3 + B * X^2 + C * X + D$$

where A, B, C, D are constants, the program will calculate the integral exactly even with only two segments.

SAMPLE RUN

The sample run illustrates the following integration

$$\int_{x=0}^{x=1} \frac{4}{1+x^2} dx$$

This integral has the theoretical value of π (pi) as the correct answer! Pi, as you may know, has the value 3.1415926535. . . Before the run is started, the above function is entered at line 5000. For reference, the elapsed time since the beginning of the run is given in parentheses after each line of output. It is in hours, minutes, and seconds. This gives you an idea of how long the program took to compute each step. However, these times are not displayed in the actual program output.

50000 Y=4/(1+X**X)

EASY CHANGES

1. You might want the program to stop calculation after the integral has been evaluated for a given number of segments. Adding the following line will cause the program to stop after the integral is evaluated for a number of segments greater than or equal to 100.

```
615 IF N>=100 THEN END
```

Of course, you may use any value you wish instead of 100.

2. Perhaps you would like to see the number of segments change at a different rate during the course of the calculation. This can be done by modifying line 620. To increase the rate of change, try

```
620 N=N*4
```

To change it at a constant (and slower) rate, try

$$620 \text{ } N=N+50$$

Be sure, however, that the value of N is always even.

MAIN ROUTINES

150 - 160	Initializes constants.
200 - 290	Displays introductory messages and warning.
300 - 310	Gets integration limits from operator.
360 - 380	Displays column headings.
400 - 420	Computes integral contribution from end points.
450 - 480	Adds contribution from one summation.
500 - 530	Adds contribution from other summation.
600 - 630	Completes integral calculation and displays it. Increases number of segments and restarts calculation.
5000 - 5999	Operator supplied subroutine to evaluate $f(x)$.

MAIN VARIABLES

N	Number of segments.
V	CHR\$ argument.
J	Loop index.
L, U	Lower, Upper integration limit of x .
DX	Width of one segment.
T	Partial result of integral.
M	Number of summations.
Z	Subtotal of summations.
A	Value of integral.
X	Current value of x .
Y	Current value of the function $y=f(x)$.

SUGGESTED PROJECTS

1. Add an additional column to the output which gives the elapsed time since the previous line was displayed. Thus, you can compare the tradeoff between additional computation time and solution accuracy. This change will involve using the PET's built-in timing variables TI and $TI\$$.

2. Research other similar techniques for numerical integration such as the simpler trapezoid rule. Then add a column of output computing the integral with this new method. Compare how the two methods converge toward the (hopefully) correct answer.
3. Modify the program to compute answers to “double precision” or greater; i.e. at least fifteen significant digits. Try the function used in the sample run to see if you can calculate pi to this high degree of precision.

SIMEQN

PURPOSE

This program solves a set of simultaneous linear algebraic equations. It is capable of handling up to fifteen equations in fifteen unknowns. This type of problem often arises in scientific and numerical work. Algebra students encounter them regularly—many “word” problems can be solved by constructing the proper set of simultaneous equations.

The equations to be solved can be written mathematically as follows:

$$\begin{array}{rcll} A_{11}X_1 + A_{12}X_2 + \dots + A_{1N}X_N & = & R_1 \\ A_{21}X_1 + A_{22}X_2 + \dots + A_{2N}X_N & = & R_2 \\ \vdots & & \vdots \\ A_{N1}X_1 + A_{N2}X_2 + \dots + A_{NN}X_N & = & R_N \end{array}$$

N is the number of equations and thus the number of unknowns also. The unknowns are denoted X_1 through X_N .

Each equation contains a coefficient multiplier for each unknown and a right-hand-side term. These coefficients (the A matrix) and the right-hand-sides (R_1 through R_N) must be constants—positive, negative, or zero. The A matrix is denoted with double subscripts. The first subscript is the equation number and the second one is the unknown that the coefficient multiplies.

HOW TO USE IT

The program will prompt you for all necessary inputs. First, it asks how many equations (and thus how many unknowns) comprise your set. This number must be at least 1 and no more than 15. Then, you must enter the coefficients and right-hand-sides for each equation. The program will request these one at a time, continually indicating which term it is expecting next.

Once it has all your inputs, the program begins calculating the solution. This may take a little while if the value of N is high. The program ends by displaying the answers. These, of course, are the values of each of the unknowns, X_1 through X_N .

If you are interested, the numerical technique used to solve the equations is known as Gaussian elimination. Row interchange to achieve pivotal condensation is employed. (This keeps maximum significance in the numbers.) Then back substitution is used to arrive at the final results. This technique is much simpler than it sounds and is described well in the numerical analysis books referenced in the bibliography.

SAMPLE PROBLEM AND RUN

Problem: A painter has a large supply of three different colors of paint: dark green, light green, and pure blue. The dark green is 30% blue pigment, 20% yellow pigment, and the rest base. The light green is 10% blue pigment, 35% yellow pigment, and the rest base. The pure blue is 90% blue pigment, no yellow pigment, and the rest base. The painter, however, needs a medium green to be composed of 25% blue pigment, 25% yellow pigment, and the rest base. In what percentages should he mix his three paints to achieve this mixture?

Solution: Let X_1 = percent of dark green to use,
 X_2 = percent of light green to use,
 X_3 = percent of pure blue to use.

The problem leads to these three simultaneous equations to solve:

$$0.3 X_1 + 0.1 X_2 + 0.9 X_3 = 0.25$$

$$0.2 X_1 + 0.35 X_2 = 0.25$$

$$X_1 + X_2 + X_3 = 1.0$$

The first equation expresses the amount of blue pigment in the mixture. The second equation is for the yellow pigment. The

third equation states that the mixture is composed entirely of the three given paints. (Note that all percentages are expressed as numbers from 0-1.) The problem leads to the following use of SIMEQN.

SAMPLE RUN

A SIMULTANEOUS LINEAR EQUATION SOLVER

HOW MANY EQUATIONS IN THE SET? 3

THE 3 UNKNOWNNS WILL BE DENOTED
X1 THROUGH X3

ENTER THE PARAMETERS FOR EQUATION 1

COEFFICIENT OF X1? .3

COEFFICIENT OF X2? .1

COEFFICIENT OF X3? .9

RIGHT HAND SIDE? .25

ENTER THE PARAMETERS FOR EQUATION 2

COEFFICIENT OF X1? .2

COEFFICIENT OF X2? .35

COEFFICIENT OF X3? 0

RIGHT HAND SIDE? .25

ENTER THE PARAMETERS FOR EQUATION 3

COEFFICIENT OF X1? 1

COEFFICIENT OF X2? 1

COEFFICIENT OF X3? 1

RIGHT HAND SIDE? 1

THE SOLUTION IS

X1= .55

X2= .4

X3= .05

READY.

Thus, the painter should use a mixture of 55% dark green, 40% light green, and 5% pure blue.

```

EASY CHANGES

You may be surprised sometime to see the program fail completely and display this message:

?DIVISION BY ZERO ERROR IN 2150

This means your input coefficients (the A array) were ill-conditioned and no solution was possible. This can arise from a variety of causes; e.g. if one equation is an exact multiple of another, or if *every* coefficient of one particular unknown is zero. If you would like the program to print a diagnostic message in these cases, add this line.

```
2145 IF A(N,N)=0 THEN PRINT"ILL-CONDITIONED
                                INPUT":STOP
```

MAIN ROUTINES

200 - 220	Clears screen and displays program title.
300 - 430	Gets input from user and calculates the solution.
500 - 530	Displays the solution.
900 - 910	Subroutine to space and separate the output.
2000 - 2180	Subroutine to calculate the solution; consisting of the following parts:
2000	Forms solution if N=1.
2010 - 2140	Gaussian elimination.
2030 - 2100	Interchanges rows to achieve pivotal condensation.
2150 - 2180	Back substitution.

MAIN VARIABLES

I,J,K,L	Loop indices and subscripts.
N	Number of equations (thus number of unknowns also).
A	Doubly dimensioned array of the coefficients.
R	Array of right-hand-sides.
V	Array of the solution.
Q	Work variable.

SUGGESTED PROJECTS

1. The program modifies the A and R arrays while computing the answer. This means the original input cannot be displayed after it is input. Modify the program to save the information and enable the user to retrieve it after the solution is given.
2. Currently, a mistake in typing input cannot be corrected once the **RETURN** key is pressed after typing a number. Modify the program to allow correcting previous input.
3. The restriction that N not be greater than 15 is due to the PET's inability to handle array subscripts outside the range 0-255. The A array is dimensioned A(N,N) which means N cannot be 16 or higher. Modify the program to allow $N > 15$ by breaking up the A array into multiple arrays. However, it is unlikely that you will have an application for the program with $N > 15$.

STATS

PURPOSE

Ever think of yourself as a statistic? Many times we lament at how we have become just numbers in various computer memories, or we simply moan at our insurance premiums. To most people, the word “statistics” carries a negative connotation. To invoke statistics is almost to be deceitful, or at least de-humanizing. But really, we all use statistical ideas regularly. When we speak of things like “she was average height” or the “hottest weather in years,” we are making observations in statistical terms. It is difficult not to encounter statistics in our lives, and this book is no exception.

Of course, when used properly, statistics can be a powerful, analytical tool. STATS analyzes a set of numerical data that you provide. It will compile your list, order it sequentially, and/or determine several statistical parameters which describe it.

This should prove useful in a wide variety of applications. Teachers might determine grades by analyzing a set of test scores. A businessman might determine marketing strategy by studying a list of sales to clients. Little leaguers always like to pore over the current batting and pitching averages. You can probably think of many other applications.

HOW TO USE IT

Before entering the data, the program will ask whether or not you wish to use identifiers with the data values. These identifiers can be anything associated with the data: e.g. names accom-

panying test scores, cities accompanying population values, corporations accompanying sales figures, etc. Hit the Y or N key to indicate yes or no regarding the use of identifiers. You do not need to hit the **RETURN** key.

Next, your data list must be entered. The program will prompt you for each value with a question mark. If identifiers are being used, you will be prompted for them before being asked for the associated data value. You may use any length character strings you desire for identifiers. However, if you limit them to a maximum of seventeen characters, the formatting of later output will be "cleaner."

Two special inputs, ***END** and ***BACK**, may be used at any time during this data input phase. They are applicable whether or not identifiers are being used. To signal the end of data, input the four character string, ***END**, in response to the (last) question mark. You must, of course, enter at least one data value.

If you discover that you have made a mistake, the five character string, ***BACK**, can be used to back up the input process. This will cause the program to re-prompt you for the previous entry. By successive uses of ***BACK** you can return to any previous position.

With the input completed, the program enters a command mode. You have four options to continue the run:

- 1) List the data in the order input
- 2) List the data in ranking order
- 3) Display statistical parameters
- 4) End the program

Simply input the number 1, 2, 3, or 4 to indicate your choice. If one of the first three is selected, the program will perform the selected function and return to this command mode to allow another choice. This will continue until you choose 4 to terminate the run. A description of the various options now follows.

Options 1 and 2 provide lists of the data. Option 1 does it in the original input order while option 2 sorts the data from highest value to lowest. In either case the identifiers, if used, will be shown alongside their associated values.

The lists are started by hitting any key when told to do so. Either list may be temporarily halted by hitting any key while the list is being displayed. This allows you to leisurely view data that might otherwise start scrolling off the screen. Simply hit

any key to resume the display. This starting and stopping can be repeated as often as desired. When the display is completed, you must again hit a key to re-enter the command mode.

Option 3 produces a statistical analysis of your data. Various statistical parameters are calculated and displayed. The following is an explanation of some that may not be familiar to you.

Three measures of location, or central tendency, are provided. These are indicators of an "average" value. The *mean* is the sum of the values divided by the number of values. If the values are arranged in order from highest to lowest, the *median* is the middle value if the number of values is odd. If it is even, the median is the number halfway between the two middle values. The *midrange* is the number halfway between the largest and smallest values.

These measures of location give information about the average value of the data. However, they give no idea of how the data is dispersed or spread out around this "average." For that we need "measures of dispersion" or as they are sometimes called, "measures of variation." The simplest of these is the *range* which is just the difference between the highest and lowest data values. Two other closely related measures of dispersion are given: the *variance* and the *standard deviation*. The variance is defined as:

$$VA = \frac{\sum_{i=1}^N (V_i - M)^2}{N - 1}$$

Here N is the number of values, V_i is value i , M is the mean value. The standard deviation is simply the square root of the variance. We do not have space to detail a lengthy discussion of their theoretical use. For this refer to the bibliography. Basically, however, the smaller the standard deviation, the more all the data tends to be clustered close to the mean value.

One word of warning the first time option 2 or 3 is selected, the program must take some time to sort the data into numerical order. The time this requires depends upon how many items are on the list and how badly they are out of sequence. Average times are twenty seconds for twenty-five items, about ninety seconds for fifty items, almost six minutes for a hundred items. The PET will pause while this is occurring, so don't think it has

hung up or fallen asleep! If you have several items on your list, this is the perfect chance to rob your refrigerator, make a quick phone call, or whatever.

SAMPLE RUN

The program describes its wares. It asks whether or not the operator wishes to use identifiers with his or her input data.

```

*****
-- CONTINUATION OPTIONS --
1) LIST DATA IN ORIGINAL ORDER
2) LIST DATA IN RANKING ORDER
3) DISPLAY STATISTICS
4) END PROGRAM

WHAT NEXT (1, 2, 3, OR 4)? 2
*****

THE DATA IN RANKING ORDER
5 TOTAL ENTRIES

WHILE THE LIST IS DISPLAYING, YOU
CAN HIT ANY KEY TO CAUSE A TEMPORARY
HALT. THE DISPLAY WILL RESUME WHEN YOU
HIT ANOTHER KEY.

HIT ANY KEY TO START THE DISPLAY.

```

The operator requests that the list be sorted into numerical order. The program waits for a key to be pressed to continue the run.

```

WHAT NEXT (1, 2, 3, OR 4)? 2
*****
THE DATA IN RANKING ORDER
5 TOTAL ENTRIES

WHILE THE LIST IS DISPLAYING, YOU
CAN HIT ANY KEY TO CAUSE A TEMPORARY
HALT. THE DISPLAY WILL RESUME WHEN YOU
HIT ANOTHER KEY.

HIT ANY KEY TO START THE DISPLAY.

```

#	VALUE	ID
1	1000	FELDMAN
2	1000	RUGG
3	1000	O'FURTH
4	1000	GABRANZO
5	1000	SAVAGE

```

HIT ANY KEY TO CONTINUE

```

The operator hits a key and is shown the data list in ranking order. Again, the program waits for the pressing of a key to continue.

```

2730 N2=Z(J+1):IF V(N1)>V(N2) THEN 2750
2740 Z(J+1)=N1:Z(J)=N2
2750 NEXT:NEXT:Z(0)=1:RETURN
2900 PRINT:PRINT"HIT ANY KEY TO CONTINUE"
2910 GET R$:IF R$="" THEN 2910
2920 RETURN

```

EASY CHANGES

1. The program is currently dimensioned to allow a maximum of 100 data items. The total storage required for the program depends on the maximum dimension parameter, MX; whether or not identifiers are being used; and if so, on the length of a typical identifier. An 8K PET will have enough storage for 100 data values with identifiers of 18 character average length. If there are more than 100 items in your application, you will need to change the value of MX in line 160 accordingly. The maximum allowable value is 255, which would necessitate this change:

160 MX=255

- However, this would not leave any room to use identifiers. An interplay results between lower setting of MX and longer average identifier length allowable. A 200 setting for MX will allow identifiers of 5 character average length. A 150 value for MX will allow identifiers of 10 character average length.
2. Because of possible conflicts with identifiers in your list, you may wish to change the special strings that signal termination of data input and/or the backing up of data input.

These are controlled by the variables E\$ and B\$, respectively. They are set in line 150. If you wish to terminate the data with /DONE/ and to back up with /LAST/ for example, line 150 should be:

```
150 B$="/LAST/":E$="/DONE/"
```

3. You may wish to see your lists sorted from smallest value to largest value instead of the other way around, as done now. This can be accomplished by changing the "greater than" sign (>) in line 2730 to a "less than" sign (<). Thus:

```
2730 N2=Z(J+1):IF V(N1)<V(N2) THEN 2750
```

This will, however, cause a few funny things to happen to the statistics. The real minimum value will be displayed under the heading "maximum" and vice-versa. Also, the range will have its correct magnitude but with an erroneous minus sign in front. To cure these afflictions, make these changes also:

```
1630 GOSUB 2700:PRINT"MINIMUM VALUE = ";V(Z(1))
```

```
1640 PRINT"MAXIMUM VALUE = ";V(Z(N))
```

```
1650 PRINT"RANGE = ";V(Z(N))-V(Z(1))
```

MAIN ROUTINES

- | | |
|-------------|---|
| 150 - 180 | Initializes constants and dimensioning. |
| 200 - 370 | Displays messages, determines if identifiers will be used. |
| 400 - 620 | Gets data from the user. |
| 700 - 710 | Checks that input contains at least one value. |
| 720 - 820 | Command mode - gets user's next option and does a GOSUB to it. |
| 1000 - 1090 | Subroutine to list data in the original order. |
| 1200 - 1340 | Subroutine to list data in ranking order. |
| 1500 - 1740 | Subroutine to calculate and display statistics. |
| 2000 - 2360 | Subroutines to display various messages. |
| 2500 - 2520 | Subroutine to allow user to temporarily start and stop display listing. |
| 2700 - 2750 | Subroutine to sort the list in ranking order. |
| 2900 - 2920 | Subroutine to detect if user has hit a key to continue. |

MAIN VARIABLES

MX	Maximum number of data values allowed.
D\$(MX)	String array of identifiers.
V(MX)	Array of the data values.
Z(MX)	Array of the sorting order.
N	Number of data values in current application.
F	Flag on identifier usage (1=yes, 0=no).
B\$	Flag string to back up the input.
E\$	Flag string to signal end of the input.
N\$	String for a null identifier.
R\$	User input string.
NM	N-1.
R	Continuation option.
NP	Number of positive values.
NN	Number of negative values.
NZ	Number of zero values.
W	Sum of the values.
SQ	Sum of the squares of the values.
M	Mean value.
MD	Median of the values.
VA	Variance.
SD	Standard deviation.
J,K	Loop indices.
N1,N2	Possible data locations to interchange during sorting.
Q	Work variable.

SUGGESTED PROJECTS

1. The sorting algorithm used in the program is efficient only when the number of list items is fairly small—less than twenty-five or so. This is because it does not do checking along the way to see when the list becomes fully sorted. If your lists tend to be longer than twenty-five items, you might wish to use another sorting algorithm more appropriate for longer lists. Try researching other sorts and incorporating them into the program. To get you started, try these changes:

```
2720 Q=0:FOR J=1 TO N-1:N1=Z(J)
2730 N2=Z(J+1):IF V(N1)>=V(N2) THEN 2750
2745 Q=1
2750 NEXT:IF Q=1 THEN 2720
2760 Z(0)=1:RETURN
```

If your lists are short, this routine will probably be a little slower than the current one. However, for longer lists it will save proportionately more and more time.

2. Because the INPUT statement is used when entering identifiers, commas cannot be used inside identifier names. Basic will ignore anything entered past the comma. This can be circumvented if you use quotes around the identifier name, but you may forget to do this. By modifying the input routine to use a series of GET commands, you can build up the identifier strings piecemeal and allow imbedded commas. Modify the appropriate routine to do this.
3. Many other statistical parameters exist to describe this kind of data. Research them and add some that might be useful to you. One such idea is classifying the data. This consists of dividing the range into a number of equal classes and then counting how many values fall into each class.

Section 6

Miscellaneous Programs

INTRODUCTION TO MISCELLANEOUS PROGRAMS

These programs show how simple programs can do interesting things. Most of them have a mathematical flavor. They are short and, as such, would be useful for study for those just learning BASIC in particular or programming in general.

Monte Carlo simulation involves programming the computer to conduct an experiment. (It doesn't involve high-stakes gambling!) PI shows how this technique can be used to calculate an approximation to the famous mathematical constant pi.

PYTHAG will find all right triangles with integral side lengths. A clever algorithm is utilized to do this.

Have you ever looked around your classroom or club meeting and wondered if any two people had the same birthdate? BIRTHDAY will show you what the surprising odds are.

Very high precision arithmetic can be done on the PET with the proper "know-how." POWERS will calculate the values of integers raised to various powers; not to the PET's "normal" nine digit precision, but up to 250 full digits of precision.

BIRTHDAY

PURPOSE

Suppose you are in a room full of people. What is the probability that two or more of these people have the same birthday? How many people have to be in the room before the probability becomes greater than 50 per cent? We are talking only about the month and day of birth, not the year.

This is a fairly simple problem to solve, even without a computer. With a computer to help with the calculations, it becomes very easy. What makes the problem interesting is that the correct answer is nowhere near what most people immediately guess. Before reading further, what do you think? How many people have to be in a room before there is better than a 50-50 chance of birthday duplication? 50? 100? 200?

HOW TO USE IT

When you RUN the program, it starts by displaying headings over two columns of numbers that will be shown. The left column is the number of people in the room, starting with one. The right column is the probability of birthday duplication.

For one person, of course, the probability is zero, since there is no one else with a possible duplicate birthday. For two people, the probability is simply the decimal equivalent of $1/365$ (note that we assume a 365 day year, and an equal likelihood that each person could have been born on any day of the year).

What is the probability of duplication when there are three people in the room? No, not just $2/365$. It's actually

$$1 - (364/365 \text{ times } 363/365)$$

This is simply one minus the probability of *no* duplicate birthdays.

The probability for four people is

$$1 - (364/365 \text{ times } 363/365 \text{ times } 362/365)$$

The calculation continues like this, adding a new term for each additional person in the room. You will find that the result (probability of duplication) exceeds .50 surprisingly fast.

The program continues with the calculation until there are 60 people in the room. You will have to STOP the program long before that to see the point where the probability first exceeds 50 per cent.

SAMPLE RUN

NO. OF PEOPLE	PROB. OF 2 OR MORE WITH SAME BIRTHDAY
1	0
2	2.7397261E-03
3	8.20416585E-03
4	.0163559124
5	.0271355736
6	.0404624834

PROGRAM LISTING

```

100 REM: COINCIDENT BIRTHDAY PROBABILITY PROBLEM
110 REM: COPYRIGHT 1978 BY TOM RUGG AND PHIL FELDMAN
120 PRINT CHR$(147)
130 PRINT"NO. OF    PROB. OF 2 OR MORE"
140 PRINT"PEOPLE    WITH SAME BIRTHDAY"
150 Q=1
160 FOR N=1 TO 60
170 PRINT N,1-Q
180 Q=Q*(365-N)/365
190 NEXT N
200 END

```

EASY CHANGES

Change the constant value of 60 in line 160 to alter the range of the number of people in the calculation. For example, change it to 100 and watch how fast the probability approaches 1.

MAIN ROUTINES

120 - 140	Displays headings.
150	Initializes Q to 1.
160 - 190	Calculates probability of no duplication, then displays probability of duplication.

MAIN VARIABLES

N	Number of people in the room.
Q	Probability of no duplication of birthdays.

SUGGESTED PROJECTS

Modify the program to allow for leap years in the calculation, instead of assuming 365 days per year.

PI

PURPOSE AND DISCUSSION

The Greek letter pi, π represents probably the most famous constant in mathematical history. It occurs regularly in many different areas of mathematics. It is best known as the constant appearing in several geometric relationships involving the circle. The circumference of a circle of radius r is $2\pi r$, while the area enclosed by the circle is πr^2 .

Being a transcendental number, pi cannot be expressed exactly by any number of decimal digits. To nine significant digits, its value is 3.14159265. Over many centuries, man has devised many different methods to calculate pi.

This program uses a valuable, modern technique known as computer simulation. The name "simulation" is rather self-explanatory; the computer performs an experiment for us. This is often desirable for many different reasons. The experiment may be cheaper, less dangerous, or more accurate to run on a computer. It may even be impossible to do in "real life." Usually, however, the reason is that the speed of the computer allows the simulation to be performed many times faster than actually conducting the real experiment.

This program simulates the results of throwing darts at a specially constructed dartboard. Consider Figure 1 which shows the peculiar square dartboard involved. The curved arc, outlining the shaded area, is that of a circle with the center in the lower left hand corner. The sides of the square, and thus the radius of the circle, are considered to have a length of 1.

Figure 1. The PI Dartboard

Suppose we were able to throw darts at this square target in such a way that each dart had an equal chance of landing anywhere within the square. A certain percentage of darts would result in "hits," i.e. land in the shaded area. The expected value of this percentage is simply the area of the shaded part divided by the area of the entire square.

The area of the shaded part is one fourth of the area the entire circle would enclose if the arc were continued to completely form the circle. Recall the area of a circle is πr^2 where r is the radius. In our case, $r=1$, and the area of the entire circle would simply be π . The shaded area of the dartboard is one fourth of this entire circle and thus has an area of $\pi/4$. The area of the square is s^2 , where s is the length of a side. On our dartboard, $s=1$, and the area of the whole dartboard is 1.

Now the expected ratio of “hits” to darts thrown can be expressed

$$\text{RATIO} = \frac{\# \text{hits}}{\# \text{thrown}} = \frac{\text{shaded area}}{\text{entire area}} = \frac{\pi/4}{1} = \frac{\pi}{4}$$

So we now have an experimental way to approximate the value of π . We perform the experiment and compute the ratio of “hits” observed. We then multiply this number by 4 and we have calculated π experimentally.

But instead of actually constructing the required dartboard and throwing real darts, we will let the PET do the job. The program “throws” each dart by selecting a separate random number between 0 and 1 for the X and Y coordinates of each dart. This is accomplished by using the built-in RND function of Basic. A “dart” is in the shaded area if $X^2 + Y^2 < 1$ for it.

So the program grinds away, continually throwing darts and determining the ratio of “hits.” This ratio is multiplied by 4 to arrive at an empirical approximation to π .

HOW TO USE IT

The program requires only one input from you. This is the “sample size for printing,” i.e. how many darts it should throw before printing its current results. Any value of one or higher is acceptable.

After you input this number, the program will commence the simulation and display its results. A cumulative total of “hits,” darts thrown, and the current approximation to π will be displayed for each multiple of the sample size.

This will continue until you press the **STOP** key. When you are satisfied with the total number of darts thrown, press the **STOP** key to terminate the program execution.

600 PRINT CHR$(147);TAB(6);
610 PRINT "A DARTBOARD PI CALCULATOR"
620 PRINT:PRINT:RETURN
700 PRINT CHR$(196);:RETURN

```

EASY CHANGES

1. If you want the program to always use a fixed sample size, change line 310 to read

310 NP=150

Of course, the value of 150 given here may be changed to whatever you wish. With this change, line 320 is not needed and may be deleted.

2. If you want the program to stop by itself after a certain number of darts have been thrown, add the following two lines:

```
315 INPUT"TOTAL # DARTS TO THROW";ND
415 IF T>=ND THEN END
```

This will ask the operator how many total darts should be thrown, and then terminate the program when they have been thrown.

MAIN ROUTINES

150 - 160	Initializes constants.
300 - 380	Gets operator input, displays column headings.
400 - 420	Calculates and displays results.
500 - 530	Throws NP darts and records number of "hits."
600 - 620	Clears screen and displays program title.
700	Draws underlining characters.

MAIN VARIABLES

T	Total darts thrown.
TH	Total "hits."
NP	Sample size for printing.
NH	Number of hits in one group of NP darts.
P	Calculated value of pi.
X,Y	Random-valued coordinates of a dart.
J	Loop index.
Q	Work variable.

SUGGESTED PROJECTS

1. Calculate the percentage error in the program's calculation of pi and display it with the other results. PET Basic includes the special variable π which gives the value of pi correct to nine digits. The percentage error, PE, can be calculated as

$$PE = 100 * ABS(P - \pi) / \pi$$

2. The accuracy of this simulation is highly dependent on the quality of the PET's random number generator. Try researching different algorithms for pseudo random number generation. Then try incorporating them into the program. Change line 510 to use the new algorithm(s). This can actually be used as a test of the various random number generators. Gruenberger's book, referenced in the bibliography, contains good material on various pseudo random number generators.

POWERS

PURPOSE

By now you have probably learned that the PET keeps track of nine significant digits when dealing with numbers. For integers less than one billion (1,000,000,000), the PET can retain the precise value of the number. But for larger integers the PET only keeps track of the most significant (leftmost) nine digits, plus the exponent. This means, of course, that there is no way you can use the PET to deal with precise integers greater than one billion, right?

Wrong.

This program calculates either factorials or successive powers of an integer, and can display precise results that are up to 250 digits long. By using a “multiple-precision arithmetic” technique, this program can tell you *exactly* what 973 to the 47th power is, for example.

HOW TO USE IT

The program first asks you how many digits long you want the largest number to be. This can be any integer from 1 to 250. So, for example, if you enter 40, you will get answers up to forty digits long.

Next you are asked for the value of N. If you respond with a value of 1, you are requesting to be shown all the factorials that will fit in the number of digits you specified. First you will get one factorial, then two factorial, and so on. In case you have

forgotten, three factorial is 3 times 2 times 1, or 6. Four factorial is 4 times 3 times 2 times 1, or 24.

If you enter an N in the range from 2 through 100,000, you are requesting the successive powers of that number up to the limit of digits you specified. So, if you provide an N of 23, you will get 23 to the first power, then 23 squared, then 23 cubed, and so on.

Finally, after it has displayed the largest number that will fit within the number of digits you entered, the program starts over. The larger the number of digits you ask for, the longer it will take the program to calculate each number.

SAMPLE RUN

The operator wants answers up to 40 digits long in the calculations of the powers of 98789. The program calculates numbers up to 98789^{40} and then asks for the number of digits again (in preparation for the next calculation the operator requests).

PROGRAM LISTING

410 GOTO 260
500 FOR J=1 TO 255:N(J)=0:NEXT
510 PRINT:GOTO 170

```

EASY CHANGES

1. To change the program so that it always uses, say, fifty digit numbers, remove lines 170 and 180, and insert this line:

```
170 M=50
```

2. To clear the screen before the output begins being displayed, change line 220 to say:

```
220 PRINT CHR$(147)
```

3. To display a blank line before each new number (to improve readability), insert this line:

```
335 PRINT
```

To double space *all* output, you should also insert another PRINT and colon just before the first PRINT in line 360.

MAIN ROUTINES

120 - 160	Displays title. Sets up array for calculations.
170 - 240	Asks for number of digits and N. Checks validity of responses. Displays heading.
250	Initializes variables for calculations.
260 - 300	Performs "carrying" in N array so each element has a value no larger than 9.
310 - 320	Scans backwards through N array for first non-zero element.
330	Checks to see if this value would be larger than the number of digits requested.
340 - 370	Displays counter and number. Goes to second line if necessary.
380 - 390	Prepares to multiply by N to get next number.
400 - 410	Multiplies each digit in N array by N. Goes back to line 260.
500 - 510	Zeroes out N array in preparation for next request. Goes back to 170.

MAIN VARIABLES

N	Array in which calculations are made.
M	Number of digits of precision requested by operator.
N	Starting value. If 1, factorials. If greater than 1, powers of N.
F	Set to zero if powers, 1 if factorials.
T	Constant value of 10.
K	Counter of current power or factorial.
J	Subscript variable.
Q,W	Temporary variables used in reducing each integer position in the N array to a value from 0 to 9.
D	Number of digits displayed so far on the current line.
N\$	String variable used to convert each digit into displayable format.

SUGGESTED PROJECTS

1. Determine the largest N that could be used without errors entering into the calculation (because of intermediate results exceeding one billion), then modify line 210 to permit values that large to be entered.
2. Create a series of subroutines that can add, subtract, multiply, divide, and exchange numbers in two arrays, using a technique like the one used here. Then you can perform high precision calculations by means of a series of GOSUB statements.

PYTHAG

PURPOSE

Remember the Pythagorean Theorem? It says that the sum of the squares of the two legs of a right triangle is equal to the square of the hypotenuse. Expressed as a formula, it is $a^2 + b^2 = c^2$. The most commonly remembered example of this is the 3-4-5 right triangle ($3^2 + 4^2 = 5^2$). Of course, there are an infinite number of other right triangles.

This program displays integer values of a, b, and c that result in right triangles.

HOW TO USE IT

To use this program, all you need to do is RUN it and watch the “Pythagorean triplets” (sets of values for a, b, and c) come out. The program displays twenty sets of values on each screen, and then waits for you to press any key (except STOP) before it continues with the next twenty. It will go on indefinitely until you press the STOP key.

The left-hand column shows the count of the number of sets of triplets produced, and the other three columns are the values of a, b, and c.

The sequence in which the triplets are produced is not too obvious, so we will explain how the numbers are generated.

It has been proved that the following technique will generate all *primitive* Pythagorean triplets. (“Primitive” means that no set is an exact multiple of another.) If you have two positive integers called R and S such that:

1. R is greater than S,
2. R and S are of opposite parity (one is odd and the other is even), and
3. R and S are relatively prime (they have no common integer divisors except 1),

then a, b, and c can be found as follows:

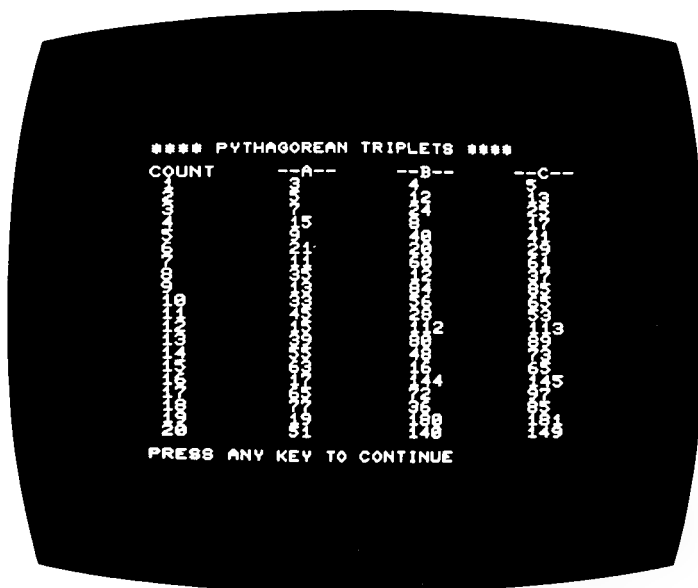

$$a = R^2 - S^2$$

$$b = 2RS$$

$$c = R^2 + S^2$$

The program starts with a value of 2 for R. It generates all possible S values for that R (starting at R-1 and then decreasing) and then adds one to R and continues. So, the first set of triplets is created when R is 2 and S is 1, the second set when R is 3 and S is 2, and so on.

SAMPLE RUN

The program generates a screen full of Pythagorean triplets, then waits for the operator to press a key to continue.

430 GET R$:IF R$="" THEN 430
440 GOSUB 350
450 D=0
460 GOTO 240

```

EASY CHANGES

1. Alter the starting value of R in line 130. Instead of 2, try 50 or 100.
2. If you want, you can change the number of sets of triplets displayed on each screen. Change the 20 in line 400 to a 10, for example. You probably won't want to try a value greater than 20, since that would cause the column headings to roll off the screen.
3. To make the program continue without requiring you to press a key for the next screen of values, insert either of these lines:

405 GOTO 440

or

405 GOTO 450

The first will display headings for each screen. The second will only display the headings at the beginning of the run.

MAIN ROUTINES

130	Initializes variables.
150	Displays the title and column headings.
180	Calculates first value of S for current R value.
190 - 210	Calculates A, B, and C.
220 - 230	Displays one line of values. Adds to counters.
240	Calculates next S value. If no more, calculates next R value.
250 - 300	Determines if R and S are relatively prime.
350 - 390	Subroutine to display title and column headings.
400 - 460	Checks if screen is full yet. If so, waits for key to be pressed.

MAIN VARIABLES

R,S	See explanation in "How To Use It."
K	Count of total number of sets displayed.
D	Count of number of sets displayed on one screen.
A,B,C	Lengths of the three sides of the triangle.
S1,B1,	Used in determining if R and S are relatively
R1,N	prime.
R\$	Key pressed by operator to continue.

SUGGESTED PROJECTS

1. In addition to displaying K, A, B, and C on each line, display R and S. You will have to squeeze the columns closer together.
2. Because this program uses integer values that get increasingly large, eventually some will exceed the PET's integer capacity and produce incorrect results. Can you determine when this will be? Modify the program to stop when this occurs.

Appendix I

Memory Usage

Each of the programs in this book will fit in a Commodore PET 2001 computer that has 8K or more of user memory. If your PET has only 4K of user memory, you'll find that the great majority of the programs will still fit in your computer with no changes. A few other programs will require minor changes that are discussed in the text of the corresponding chapters.

Based on our estimates, here are the programs that will *not* fit in a 4K PET:

Programs that will probably fit in a 4K PET if you make fairly extensive changes:

(for example, eliminating unnecessary spaces from program statements, reducing the length of text literals where possible, deleting REM statements, removing unneeded options, reducing array sizes where possible, etc.)

CHECKBOOK, WARI

Programs that are too large to be compressed into 4K:

DECIDE, JOT, STATS
